RAREFACTIONS IN THE DAFERMOS REGULARIZATION OF A SYSTEM OF CONSERVATION LAWS

STEPHEN SCHECTER AND PETER SZMOLYAN

Abstract. We construct self-similar solutions of the Dafermos regularization of a system of conservation laws near structurally stable Riemann solutions composed of Lax shocks and rarefactions, with all waves possibly large. The construction requires blowing up a manifold of gain-of-stability turning points in a geometric singular perturbation problem, as well as a new exchange lemma to deal with the remaining hyperbolic directions.

1. Introduction

This paper is the last in a series of three; the others are [20] and [21]. An introduction to the series is in [20]. We construct self-similar solutions of the Dafermos regularization of a system of conservation laws near structurally stable Riemann solutions composed of Lax shocks and rarefactions, with all waves possibly large. The construction requires blowing up a manifold of gain-of-stability turning points in a geometric singular perturbation problem. In addition, it requires a new exchange lemma to deal with the remaining hyperbolic directions. The latter is a consequence of the General Exchange Lemma from [21].

In this introduction, we briefly describe the conservation law background, and we describe some solutions near gain-of-stability turning points in order to help the reader’s intuition.

A system of conservation laws in one space dimension is a partial differential equation of the form

\[ u_T + f(u)_X = 0, \]

with \( X \in \mathbb{R}, u \in \mathbb{R}^n, \) and \( f : \mathbb{R}^n \to \mathbb{R}^n. \) For background on this class of equations, see, for example, [24]. An important initial value problem is the Riemann problem, which has piecewise constant initial conditions:

\[ u(X,0) = \begin{cases} u_L & \text{for } X < 0, \\ u_R & \text{for } X > 0. \end{cases} \]

One looks for a solution of the Riemann problem in the self-similar form \( u(x) = \frac{x}{T}. \) Substitution into (1.1) yields the ordinary differential equation

\[ (A(u) - xI)u_x = 0, \]

with \( A(u) = Df(u) \), an \( n \times n \) matrix. Boundary conditions are \( u(-\infty) = u_L, u(\infty) = u_R. \) Solutions are allowed to have constant parts, continuously changing parts (rarefaction waves), and certain jump discontinuities (shock waves).

Date: March 26, 2007.

Key words and phrases. conservation laws, Riemann problem, geometric singular perturbation theory, loss of normal hyperbolicity, blow-up.

This work was supported in part by the National Science Foundation under grant DMS-0406016.
The Dafermos regularization of (1.1) is
\[ u_T + f(u)_X = \epsilon Tu_{XX}. \] (1.4)
Solutions that have the self-similar form \( u(x), \ x = \frac{x}{x} \), satisfy the ordinary differential equation
\[ (A(u) - xI)u_x = \epsilon u_{xx}, \] (1.5)
a “viscous perturbation” of (1.3). Solutions of (1.5) that approach constants at \( x = \pm \infty \) and have \( u'(\pm \infty) = 0 \) are called Riemann-Dafermos solutions.

It is known under a variety of assumptions that, for small \( \epsilon > 0 \), near a solution of the Riemann problem (1.1)–(1.2) is a Riemann-Dafermos solution that satisfies the same boundary conditions [2, 27, 18, 16, 23]. Riemann-Dafermos solutions are smoothed-out versions of the corresponding Riemann solutions. This conclusion holds, for example, whenever \( u_L \) is close to \( u_R \) [27]. In addition, it holds for arbitrary \( u_L \) and \( u_R \) if (1) the Riemann solution consists entirely of shock waves, (2) each shock wave satisfies the viscous profile criterion (see Section 2) for the viscosity \( u_{xx} \), and (3) the Riemann solution is structurally stable; see [18].

We shall show that the same conclusion holds for arbitrary \( u_L \) and \( u_R \) provided the Riemann solution is structurally stable and consists entirely of Lax shock waves and rarefaction waves. If rarefaction waves are present, this case is not covered by the above results.

The ODE (1.5) can be written as the nonautonomous system
\[ \epsilon u_x = v, \]
\[ \epsilon v_x = (A(u) - xI)v, \]
Setting \( x = x_0 + \epsilon t \), and using a dot to denote derivative with respect to \( t \), we obtain the autonomous system
\[ \dot{u} = v, \] (1.6)
\[ \dot{v} = (A(u) - xI)v, \] (1.7)
\[ \dot{x} = \epsilon, \] (1.8)
with \( (u, v, x) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R} \). The boundary conditions become
\[ (u, v, x)(-\infty) = (u_L, 0, -\infty), \quad (u, v, x)(\infty) = (u_R, 0, \infty). \] (1.9)
It turns out that a solution of the Riemann problem (1.1)–(1.2) can be regarded as a singular solution \( (\epsilon = 0) \) of the boundary value problem (1.6)–(1.9). Riemann-Dafermos solutions, on the other hand, correspond to true solutions of (1.6)–(1.9) with \( \epsilon > 0 \). Therefore, to show the existence of Riemann-Dafermos solutions near a given Riemann solution, one can try to construct true solutions of (1.6)–(1.9), with \( \epsilon > 0 \) small, near certain singular solutions.

Note that for every \( \epsilon \), \( ux \)-space is invariant under (1.6)–(1.8). On \( ux \)-space, the system reduces to \( \dot{u} = 0, \dot{x} = \epsilon \), so for \( \epsilon = 0 \), \( ux \)-space consists of equilibria. The linearization of (1.6)–(1.8) at one of these equilibria has the matrix
\[ \begin{pmatrix} 0 & I \\ 0 & A(u) - xI \\ 0 & 0 \end{pmatrix}. \quad (1.10) \]
This matrix has an eigenvalue 0 with multiplicity \( n + 1 \) (the eigenspace is \( ux \)-space), plus the eigenvalues of \( A(u) - xI \).
A common assumption in the study of conservation laws is strict hyperbolicity: for all $u$ in a region of interest, $A(u)$ has $n$ distinct real eigenvalues $\lambda_1(u) < \ldots < \lambda_n(u)$. Under this assumption, the eigenvalues of $A(u) - xI$ are $\lambda_i(u) - x$, $i = 1, \ldots, n$. Therefore, for $\epsilon = 0$, $ux$-space loses normal hyperbolicity along the codimension-one surfaces $x = \lambda_i(u)$, $i = 1, \ldots, n$.

As one crosses one of these surfaces along a line with $u$ constant and $x$ increasing, the eigenvalue $\lambda_i(u) - x$ changes from positive to negative (gain of stability).

For a small $\delta > 0$, let us consider $I_{uL} = \{(u,v,x) : u = u_L, v = 0, x < \lambda_1(u) - \delta\}$. See Figure 1.1. For each $\epsilon$, it is invariant and lies in the normally repelling invariant manifold $\{(u,v,x) : v = 0, x < \lambda_1(u) - \delta\}$. Hence it has an unstable manifold $W^u_\epsilon(I_{uL})$ of dimension $n+1$. Similarly, $I_{uR} = \{(u,v,x) : u = u_R, v = 0, \lambda_n(u) + \delta < x\}$ has a stable manifold $W^s_\epsilon(I_{uR})$ of dimension $n+1$. For $\epsilon > 0$, solutions of (1.6)–(1.9) lie in $W^u_\epsilon(I_{uL}) \cap W^s_\epsilon(I_{uR})$.

Notice that two manifolds of dimension $n+1$ in $\mathbb{R}^{2n+1}$, if they intersect, will typically intersect in curves. To find solutions of (1.6)–(1.9), one should follow $W^u_\epsilon(I_{uL})$ forward by the flow for $\epsilon > 0$ until it meets $W^s_\epsilon(I_{uR})$ (if it does).

**Figure 1.1.** For $\epsilon > 0$, an intersection of $W^u_\epsilon(I_{uL})$ and $W^s_\epsilon(I_{uR})$ gives a solution of the boundary value problem. The figure does not show the complications that typically occur in tracing $W^u_\epsilon(I_{uL})$ forward.

If the solution of the Riemann problem (1.1)–(1.2) consists only of shock waves, then for small $\epsilon > 0$, the relevant portion of $W^u_\epsilon(I_{uL})$ does not pass near any of the surfaces $v = 0$, $x = \lambda_i(u)$, where normal hyperbolicity is lost, so it can be tracked when it passes near $v = 0$ using the usual Exchange Lemma [18]. If, however, the Riemann solution includes a rarefaction wave of the $i$th family, then the relevant portion of $W^u_\epsilon(I_{uL})$ passes near the surface $v = 0$, $x = \lambda_i(u)$ [23]. Thus we have the problem of tracking a manifold of solutions as it passes near a surface of gain-of-stability turning points. In the present paper we show how to do this, and we apply the result to finding solutions of the boundary value problem (1.6)–(1.9).
For \( \epsilon = 0 \), at a point \((u, v, x)\) with \( v = 0 \) and \( x = \lambda_1(u) \), the matrix (1.10) has the eigenvalue 0 with multiplicity \( n + 2 \), and \( n - 1 \) real nonzero eigenvalues. If \( n \geq 2 \), the analysis of the flow near such a point has two parts: first, the analysis of the flow on a collection of normally hyperbolic invariant manifolds \( K_\epsilon \) of dimension \( n + 2 \), each of which properly contains an open subset of \( ax\)-space; second, application of the General Exchange Lemma from [21] to deal with the hyperbolic directions. For \( n = 1 \), the second step is not necessary; this was the situation in [23].

To help the reader’s intuition, Figure 1.2 indicates the type of solution in which we are interested in the case \( n = 1 \), in which case \( \lambda_1'(u) = f''(u) > 0 \) for \( u_L \leq u \leq u_R \). The figure shows a singular solution, which consists of the lines \( u = u_L, v = 0, x < \lambda_1(u_L) \) and \( u = u_R, v = 0, \lambda_1(u_R) < x \), together with the curve \( u_L \leq u \leq u_R, v = 0, x = \lambda_1(u) \). For small \( \epsilon > 0 \) there is an actual solution \((u_\epsilon(t), v_\epsilon(t), \epsilon t)\) just above this one that approaches \((u_L, 0, -\infty)\) as \( t \to -\infty \), and approaches \((u_R, 0, \infty)\) as \( t \to \infty \). Such a solution lies in \( W^u_\epsilon(I_{u_L}) \cap W^s_\epsilon(I_{u_R}) \). Other solutions in \( W^u_\epsilon(I_{u_L}) \) with \( v > 0 \) follow along the curve \( x = \lambda_1(u) \) for different lengths before leaving, hence approach different right states. Such solutions can be proved to exist using the blowing-up construction discussed below. Intuitively, for small \( \epsilon > 0 \), if a solution is close the curve \( u_L \leq u \leq u_R, v = 0, x = \lambda_1(u) \), but slightly above it, \( x \) increases slowly (because \( \dot{x} = \epsilon \)) and \( u \) increases slowly (because \( u = v \)), so the solution moves along the curve.

**Figure 1.2.** A singular solution with \( n = 1 \).

We begin the paper by constructing self-similar solutions of the Dafermos regularization in Section 2. The construction uses the exchange lemma we shall prove. In Section 3 we state the exchange lemma to be proved and outline the proof. In Section 4 we derive the differential equations on a normally hyperbolic invariant manifold. In Section 5 we analyze the reduced flow by blowing-up, and in Section 6 we use the blow-up to track solutions in the normally hyperbolic invariant manifold as they pass the manifold of turning points. In Section 7 we use our analysis of the flow on the the normally hyperbolic invariant manifold to prove an exchange lemma for dealing with the remaining hyperbolic directions.

2. CONSTRUCTION OF RIEMANN-DAFERMOS SOLUTIONS

2.1. Conservation laws. Consider the system of conservation laws (1.1) and its viscous regularization

\[
u_T + f(u)_X = u_{XX}.
\] (2.1)
Let $A(u) = Df(u)$. We assume strictly hyperbolicity on $\mathbb{R}^n$. We denote the eigenvalues of $A(u)$ by $\lambda_1(u) < \lambda_2(u) < \ldots < \lambda_n(u)$, and we denote corresponding eigenvectors by $r_i(u)$, $i = 1, \ldots, n$.

For notational convenience we let $\lambda_0(u) = -\infty$ and $\lambda_{n+1}(u) = \infty$.

We assume that (1.1) is genuinely nonlinear, i.e., $D\lambda_i(u)r_i(u) \neq 0$ for all $i = 1, \ldots, n$ and for all $u \in \mathbb{R}^n$. Then we can choose $r_i(u)$ so that

$$D\lambda_i(u)r_i(u) = 1.$$ 

2.2. Rarefactions. A rarefaction wave is a solution of (1.1) of the form $u(x)$, $x = \frac{t}{s} \in [a, b]$, with $a < b$ and $u'(x) \neq 0$ for all $x \in [a, b]$. Then $u(x)$ is a solution of the ordinary differential equation

$$(A(u) - xI)u_x = 0$$

with $u_x \neq 0$. Notice that each $x$ must be an eigenvalue of $A(u(x))$. In particular, a rarefaction of the $i$th family has $x = \lambda_i(u(x))$. Given $u_-$, denote the solution of the initial value problem

$$u_x = r_i(u), \quad u(\lambda_i(u_-)) = u_-,$$

by $\psi_i(u_-, x)$. Then a rarefaction of the $i$th family with left state $u_-$ is just $\psi_i(u_-, x)$, $\lambda_i(u_-) \leq x \leq b$, with $\lambda_i(u_-) < b$.

2.3. Traveling waves. A traveling wave with speed $s$ is a solution of (2.1) of the form $u(t)$, $t = X - sT$, $-\infty < t < \infty$. Hence $u(t)$ is a solution of the ordinary differential equation

$$(A(u) - sI)u_t = u_{tt}.$$ (2.3)

We shall always require constant boundary conditions:

$$u(-\infty) = u_-, \quad u(\infty) = u_+, \quad u'(\pm \infty) = 0.$$ (2.4)

Integrating (2.3) from $-\infty$ to $t$ and using the boundary conditions at $-\infty$, we obtain

$$u_t = f(u) - f(u_-) - s(u - u_-).$$ (2.5)

The system (2.5) has an equilibrium at $u_-$, and it has an equilibrium at $u_+$ provided the Rankine-Hugoniot condition is satisfied:

$$f(u_+) - f(u_-) - s(u_+ - u_-) = 0.$$ (2.6)

Thus there is traveling wave solution of (2.1) with left state $u_-$, speed $s$, and right state $u_+$ if and only if (2.6) is satisfied and (2.5) has a heteroclinic solution $u(t)$ from $u_-$ to $u_+$.

2.4. Shock waves. Let $x = \frac{X}{T}$, let $s \in \mathbb{R}$, and consider the function

$$u(x) = \begin{cases} u_- & \text{if } x < s, \\ u_+ & \text{if } x > s. \end{cases}$$ (2.7)

We shall call (2.7) a shock wave with speed $s$, and admit it as a solution of (1.1), if the viscous system (2.1) has a traveling wave solution $u(t)$ with the same left state, speed, and right state. The traveling wave $u(t)$ is a viscous profile for the shock wave (2.7), for the the viscosity $u_{xx}$. We associate with each shock wave a fixed viscous profile.

For each $i = 1, \ldots, n$, the shock wave (2.7) is a Lax $i$-shock if $\lambda_{i-1}(u_-) < s < \lambda_i(u_-)$ and $\lambda_i(u_+) < s < \lambda_{i+1}(u_+)$. It is regular if, for the system (2.5), $W^*(u_-)$ meets $W^*(u_+)$ transversally along the viscous profile $u(t)$. Notice that $u_-$ and $u_+$ are hyperbolic equilibria.
of \((2.5)\), \(W^n(u_-)\) has dimension \(n - i + 1\), and \(W^*(u_+)\) has dimension \(i\). Hence a transversal intersection has dimension one.

2.5. **Classical Riemann solutions.** An \(n\)-wave classical Riemann solution of \((1.1)\) is a function \(u^*(x), x = \frac{\xi}{\Delta}\), with the following property. Let \(s_0^* = -\infty\) and \(a^*_{i+1} = \infty\). Then there is a sequence of numbers \(a_i^* \leq s_1^* < a_2^* \leq s_2^* \leq \ldots < a_n^* \leq s_n^*\), and a sequence of points \(u_0^*, u_1^*, \ldots, u_n^*\), such that

1. For \(i = 0, \ldots, n\), if \(s_i^* < x < a_{i+1}^*\), then \(u(x) = u_i^*\).
2. If \(a_i^* < s_i^*\), then \(u^*[a_i^*, s_i^*] \) is a rarefaction of the \(i\)th family. Moreover, \(u^*(a_i^*) = u_{i-1}^*\) and \(u(s_i^*) = u_i^*\).
3. If \(a_i^* = s_i^*\), the triple \((u_{i-1}^*, s_i^*, u_i^*)\) is a Lax \(i\)-shock.

Thus \(u^*(x)\) has a jump discontinuity whenever \(a_i^* = s_i^*\). We will take \(u^*(x)\) to be undefined at such points. If \(a_i^* = s_i^*\), we denote the corresponding viscous profile by \(q_i(t)\). If \(u_0^* = u_L\) and \(u_n^* = u_R\), then \(u^*(x)\) is a solution of the Riemann problem \((1.1) - (1.2)\).

2.6. **Structural stability.** Given an \(n\)-wave classical Riemann solution \(u^*(x)\), define functions \(G_i : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}^n, i = 1, \ldots, n\), as follows:

1. If \(a_i^* < s_i^*\), \(G_i(u_-, s, u_+) = u_+ - \psi(u_-, s)\).
2. If \(a_i^* = s_i^*\), \(G_i(u_-, s, u_+) = f(u_+) - f(u_-) - s(u_+ - u_-)\).

Define \(G : \mathbb{R}^{n^2+2n} \rightarrow \mathbb{R}^{n^2}\) by

\[
G(u_0, s_1, u_1, s_2, u_2, \ldots, u_{n-1}, s_n, u_n) = (G_1(u_0, s_1, u_1), G_2(u_1, s_2, u_2), \ldots, G_n(u_{n-1}, s_n, u_n)).
\]

Let \(u^* = (u_0^*, s_1^*, u_1^*, s_2^*, u_2^*, \ldots, u_{n-1}^*, s_n^*, u_n^*)\). (We hope this reuse of the symbol \(u^*\) will not be confusing.) Then \(G(u^*) = 0\). If all shock waves are regular, then nearby solutions of \(G = 0\) also define \(n\)-wave classical Riemann solutions with the same sequence of rarefaction and shock waves. The Riemann solution \(u^*(x)\) is said to be **structurally stable** if all shock waves are regular and the restriction of \(DG(u^*)\) to the \(n^2\)-dimensional space of vectors with \(\bar{u}_0 = \bar{u}_n = 0\) is invertible. In this case, for each \((u_0, u_n)\) near \((u_0^*, u_n^*)\), there is an \(n\)-wave classical Riemann solution with left state \(u_0\), right state \(u_n\), and the same sequence of rarefaction and shock waves.

For \(i = 0, \ldots, n\), let \(O_i\) be a small neighborhood of \(u_i^*\) in \(\mathbb{R}^n\), and for \(i = 1, \ldots, n\), let \(I_i\) be a small neighborhood of \(s_i^*\) in \(\mathbb{R}\).

For \(i = 1, \ldots, n\), define \(W_i : O_{i-1} \times I_i \rightarrow \mathbb{R}^n\) as follows: \(W_i(u_{i-1}, x_i)\) is the solution \(u_i\) near \(u_i^*\) of the equation \(G_i(u_{i-1}, x_i, u_i) = 0\). There is a unique such solution by the Implicit Function Theorem.

For \(i = 0, \ldots, n\), we inductively define subsets \(R_i\) of \(O_i\) as follows:

1. \(R_0 = \{u_0^*\}\).
2. For \(i = 1, \ldots, n\), \(u_i \in O_i\) is in \(R_i\) provided there exist \(u_{i-1} \in R_{i-1}\) and \(x_i \in I_i\) such that \(W_i(u_{i-1}, x_i) = u_i\).

**Proposition 2.1.** Let \(u^*(x)\) be an \(n\)-wave classical Riemann solution that is structurally stable. Then:

1. For \(i = 0, \ldots, n\), \(R_i\) is a manifold of dimension \(i\), and \(u_i^* \in R_i\).
2. For \(i = 1, \ldots, n\), \(W_i\) maps an open subset of \(R_{i-1} \times I_i\) diffeomorphically onto \(R_i\).

Proposition 2.1 is an easy consequence of our assumption on \(DG(u^*)\).
Suppose the \( i \)th wave of the Riemann solution \( u^*(x) \) is a shock wave. Then for \((u_{i-1}, x_i) \in R_{i-1} \times I_i\), the traveling wave equation

\[
\dot{u} = f(u) - f(u_{i-1}) - x_i(u - u_{i-1})
\]  

(2.8)

has a connecting orbit \( u(t) \) from \( u_{i-1} \) to \( u_i = W_i(u_{i-1}, x_i) \) near \( q_i(t) \); moreover, the \((n-i+1)\)-dimensional unstable manifold of \( u_{i-1} \) and the \( i \)-dimensional stable manifold of \( u_i \) meet transversally along this orbit.

2.7. **Dafermos regularization.** We consider the Dafermos regularization of (1.1) with viscosity \( u_{xx} \), namely (1.4). We recall that a Riemann-Dafermos solution is a solution of the autonomous system (1.6)–(1.8) that satisfy analogous boundary conditions.

2.8. **Dafermos ODE with \( \epsilon = 0 \).** We consider (1.6)–(1.8) with \( \epsilon = 0 \):

\[
\dot{u} = v, \quad (2.9)
\]

\[
\dot{v} = (A(u) - xI)v, \quad (2.10)
\]

\[
\dot{x} = 0, \quad (2.11)
\]

We note that the \((n+1)\)-dimensional plane \( v = 0 \) consists of equilibria, and the functions \( x \) and \( f(u) - xu - v \) are first integrals. They have the following significance. Fix a number \( s \). If we restrict (2.9)–(2.10) to the \( 2n \)-dimensional invariant set \( x = s \), we obtain the second-order traveling wave equation (2.3), converted to a first-order system by setting \( v = u_t \). Now choose \( u_- \) and let \( w = f(u_-) - su_- \). Then \( \{(u, v, x) : x = s \text{ and } v = f(u) - su - v\} \) is invariant and has dimension \( n \). Parameterizing it by \( u \), the system (2.9)–(2.11) reduces to the integrated traveling wave equation (2.5).

In particular, (2.5) has a heteroclinic solution \( u(t) \) from \( u_- \) to \( u_+ \) if and only if the system (2.9)–(2.11) has a heteroclinic solution \((u(t), \dot{u}(t), s)\) from \((u_-, 0, s)\) to \((u_+, 0, s)\).

At an equilibrium \((u, 0, x)\) of (2.9)–(2.11), the matrix (1.10) of the linearization has the eigenvalues \( \lambda_i(u) - x, i = 1, \ldots, n \), and 0 repeated \( n+1 \) times. Then \(ux\)-space, the set of equilibria for (2.9)–(2.11), decomposes as follows.

- For \( i = 0, \ldots, n \), let

\[
E_i = \{(u, v, x) : v = 0 \text{ and } \lambda_i(u) < x < \lambda_{i+1}(u)\}.
\]

Each \( E_i \) is an \((n+1)\)-dimensional manifold of equilibria of (2.9)–(2.11). At \((u, 0, x)\) in \( E_i \), the linearization of (2.9)–(2.11) has \( i \) negative eigenvalues \( \lambda_k(u) - x, k = 1, \ldots, i \); \( n-i \) positive eigenvalues \( \lambda_k(u) - x, k = i+1, \ldots, n \); and the semisimple eigenvalue 0 with multiplicity \( n+1 \).

- For \( i = 1, \ldots, n \), let

\[
F_i = \{(u, v, x) : v = 0 \text{ and } x = \lambda_i(u)\}.
\]

Each \( F_i \) is an \( n \)-dimensional manifold of equilibria of (2.9)–(2.11). At \((u, 0, x)\) in \( E_i \), the linearization of (2.9)–(2.11) has \( i-1 \) negative eigenvalues, \( n-i \) positive eigenvalues, and the semisimple eigenvalue 0 with multiplicity \( n+2 \).
2.9. **Singular solution.** Suppose the Riemann problem (1.1)–(1.2) has the structurally stable $n$-wave classical Riemann solution $u^*(x)$, with $u^*_0 = u_L$ and $u^*_n = u_R$. We define the following curves in $w_x$-space:

- For $i = 0, \ldots, n$, let
  \[ L_i = \{(u, v, x) : u = u^*_i, v = 0, s^*_i < x < a^*_i + 1\} \]

- For $i = 1, \ldots, n$:
  - If $a^*_i < s^*_i$, let $\Gamma_i = \{(u, v, x) : u = u^*(x), v = 0, a^*_i < x \leq s^*_i\}$.
  - If $a^*_i = s^*_i$, let $\Gamma_i = \{(u, v, x) : u = q_i(t), v = q_i(t), x = s^*_i\} \cup \{(u^*_i, 0, s^*_i), (u^*_i, 0, s^*_i)\}$.

Note that for each $i$, $L_i \subset E_i$, and for each $i$ for which $a^*_i < s^*_i$, $\Gamma_i \subset F_i$.

The singular solution of the boundary value problem (1.6)–(1.9) is then $L_0 \cup \Gamma_1 \cup L_1 \cup \ldots \cup L_{n-1} \cup \Gamma_n \cup L_n$. It corresponds to the Riemann solution, together with the viscous profiles of the shock waves.

2.10. **Riemann-Dafermos solution.** We continue to consider the Riemann solution $u^*(x)$ of the previous subsection. Let $\delta > 0$ be small. Let $N_0 = \{(u, v, x) : u \in R_0, v = 0, -\infty < x \leq \lambda_1(u) - \delta\}$. For $i = 1, \ldots, n - 1$, let $N_i = \{(u, v, x) : u \in R_i, v = 0, s^*_i + \delta \leq x \leq \lambda_{i+1}(u) - \delta\}$, and $N_n = \{(u, v, x) : u \in R_n, v = 0, s^*_n + \delta \leq x < \infty\}$.

By Proposition 2.1, each $N_i$ is a manifold of dimension $i + 1$. Note that each $N_i$ is locally invariant, and each $W^a_u(N_i)$ has dimension $(i + 1) + (n - i) = n + 1$.

**Proposition 2.2.** For $i = 1, \ldots, n$:

1. $W^a_u(u^*_{i-1}, 0, s^*_i)$ meets $W^a_u(E_i)$ transversally along the curve $(u, v, x) = (q_i(t), q_i(t), s^*_i)$.

2. $W^a_u(N_{i-1})$ meets $W^a_u(E_i)$ transversally near the curve $(u, v, x) = (q_i(t), q_i(t), s^*_i)$.

3. Near the curve $(u, v, x) = (q_i(t), q_i(t), s^*_i)$, the projection of $W^a_u(N_{i-1}) \cap W^a_u(E_i)$ to $E_i$, along stable fibers of $W^a_u(E_i)$, is the $i$ dimensional manifold $\{(u, v, x) : u \in R_i, v = 0, 0 < x < s_i(u)\}$, where $s_i(u)$ is just the value of $x$ for which there exists $u_{i-1} \in R_{i-1}$ with $W(u_{i-1}, x) = u$.

(1) follows from the fact that the $i$th shock wave is regular. Note that $W^a_u(u^*_{i-1}, 0, s^*_i)$ has dimension $n - i + 1$ and $W^a_u(E_i)$ has dimension $n + 1 + i$, so the intersection has dimension $(n - i + 1) + (n + 1 + i) - (2n + 1) = 1$: it is the given curve. (2) and (3) are consequences of (1). See [18] for details.

Recall the sets $I^L_u$ and $I^R_u$ defined in the Introduction. They are subsets of $L_0$ and $L_n$ respectively.

**Proposition 2.3.** Let $f$ be $C^s$ with $s$ sufficiently large. For $\delta > 0$ sufficiently small, if $\epsilon > 0$ is sufficiently small, then for each $i = 0, \ldots, n$, part of $W^a_u(I^L_u)$ is $C^1$-close to the $\delta$-neighborhood of $N_i$ in $W^a_u(N_i)$. (For $i = n$, $W^a_u(N_n) = N_n$, so we are simply saying that part of $W^a_u(I^L_u)$ is $C^1$-close to $N_n$.)

**Proof.** The proof is by induction on $i$. The statement is trivially true for $i = 0$; in fact, the $\delta$-neighborhood of $N_0$ in $W^a_u(N_0)$ is a subset of $W^a_u(I^L_u)$. Suppose the statement is true for $i = k - 1$, with $1 \leq k \leq n$.

If the $k$th wave in the Riemann solution is a shock wave, then $W^a_u(N_{k-1})$ meets $W^a_u(E_k)$ transversally by Proposition 2.2, and the statement follows from the Jones-Tin Exchange Lemma (Theorem 2.3 of [21]). In the Jones-Tin Exchange Lemma, we can take $M_0$ to be a cross-section of $W^a_u(N_{k-1})$ and the other $M$’s to be cross-sections of $W^a_u(I^L_u)$ nearby; assumption (JT3) of the Jones-Tin Exchange Lemma follows from Proposition 2.2 (1).
If the $k$th wave in the Riemann solution is a rarefaction wave, the result follows from Theorem 3.1, to be proved in this paper. In that theorem we again take $M_0$ to be a cross-section of $W^o_0(N_{k-1})$ and the other $M_i$’s to be cross-sections of $W^o_0(I_{u_k})$ near $U_*$ is an open subset of $E_{k-1}$. Thus in assumption (R5) of Theorem 3.1 we have $x_* = 0$. We remark that when $x_* = 0$, the differentiability requirements of Theorem 3.1 are reduced from $C^{r+11}$ to $C^{r+8}$, because part of the proof (Subsection 6.1) is not needed.

In both cases the closeness is much greater than $C^4$ for $s$ sufficiently large, which allow the inductive argument to continue. 

\begin{proof}
For small $\epsilon > 0$, there is, for the same $u_L$ and $u_R$, a Riemann-Dafermos solution near the singular solution defined in Subsection 2.9.

\begin{enumerate}
\item[(R1)] For all $u \in U$, $A(u)$ has a simple real eigenvalue $\lambda(u)$.
\item[(R2)] There are numbers $\tilde{\lambda} < 0 < \tilde{\mu}$ such that for all $u \in U$, $A(u)$ has $k$ eigenvalues with real part less than $\lambda(u) + \tilde{\lambda}$ and $l$ eigenvalues with real part greater than $\lambda(u) + \tilde{\mu}$.
\end{enumerate}

We shall consider (1.6)–(1.8) only on $\{(u, v, x) : u \in U\}$. 

Let $E = \{(u, v, x) : u \in U \text{ and } v = 0\}$, which is invariant for each $\epsilon$. For $\epsilon = 0$, $E$ is an $(n + 1)$-dimensional manifold of equilibria. (R1)–(R2) imply that $E$ fails to be normally hyperbolic along the $n$-dimensional surface $\{(u, v, x) : u \in U, v = 0, \text{ and } x = \lambda(u)\}$. More precisely, as one crosses this surface along a line with $u$ constant and $x$ increasing, an eigenvalue $\lambda(u) - x$ changes from positive to negative (gain of stability). On the surface, there are $k$ eigenvalues with real part in $(-\infty, \tilde{\lambda})$ and $l$ eigenvalues with real part in $(\tilde{\mu}, \infty)$.

Let $\tilde{r}(u)$ be an eigenvector of $A(u)$ for the eigenvalue $\lambda(u)$. Assume

\begin{enumerate}
\item[(R3)] For all $u \in U$, $D\lambda(u)\tilde{r}(u) \neq 0$.
\end{enumerate}

In the case of systems (1.6)–(1.8) with $u, v, x \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$ and $A(u)$ an $n \times n$ matrix that is a $C^{r+11}$ function of $u$, $r \geq 1$. We do not require that $A(u) = Df(u)$ for some function $f$.

Let $n = k + l + 1$. Let $U$ be an open subset of $u$-space with the following properties:

\begin{enumerate}
\item[(R1)] For all $u \in U$, $A(u)$ has a simple real eigenvalue $\lambda(u)$.
\item[(R2)] There are numbers $\tilde{\lambda} < 0 < \tilde{\mu}$ such that for all $u \in U$, $A(u)$ has $k$ eigenvalues with real part less than $\lambda(u) + \tilde{\lambda}$ and $l$ eigenvalues with real part greater than $\lambda(u) + \tilde{\mu}$.
\end{enumerate}

We consider the system (1.6)–(1.8) with $(u, v, x) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$ and $A(u)$ an $n \times n$ matrix that is a $C^{r+11}$ function of $u$, $r \geq 1$. We do not require that $A(u) = Df(u)$ for some function $f$. 

To discuss the passage of a manifold of solutions of (1.6)–(1.8) near a manifold of turning points, we shall generalize slightly the situation previously described, and pay closer attention to degree of differentiability.

We consider the system (1.6)–(1.8) with $(u, v, x) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$ and $A(u)$ an $n \times n$ matrix that is a $C^{r+11}$ function of $u$, $r \geq 1$. We do not require that $A(u) = Df(u)$ for some function $f$.
Then for each \( u \in U \) we can choose an eigenvector \( r(u) \) for the eigenvalue \( \lambda(u) \) such that 
\[
(R3') \quad D\lambda(u)r(u) = 1.
\]
Let \( \phi(t, u) \) be the flow of \( \dot{u} = r(u) \). Since \( A(u) \) is \( C^{r+11} \), so are \( \lambda(u) \), \( r(u) \), and \( \phi(t, u) \).

Let \( u_\epsilon \in U \). Choose \( t^* > 0 \) such \( \psi(t, u_\epsilon) \in U \) for \( 0 \leq t \leq t^* \). Let \( u^* = \psi(t^*, u_\epsilon) \). By (R3'), 
\[
\lambda(u^*) = \lambda(u_\epsilon) + t^*.
\]
Choose a number \( \beta_0 > 0 \) such that 
\[
\tilde{\lambda} + \tilde{\mu} + r\beta_0 < 0 < \tilde{\mu} - \max(7, 2r + 2)\beta_0.
\] (3.1)
(We may have to first adjust the numbers \( \tilde{\lambda} \) and \( \tilde{\mu} \) used in (R2) to make this possible.)

Choose numbers \( x_\epsilon \) and \( x^* \) such that 
\[
\lambda(u^*) - \beta_0 < x_\epsilon < \lambda(u_\epsilon) \quad \text{and} \quad \lambda(u_\epsilon) < x^* < \lambda(u^*) + \beta_0.
\]

See Figure 3.1.

**Figure 3.1.** Notation of this section. For small \( \epsilon > 0 \), there is a solution near the thick line from \((u, v, x) = (u_\epsilon, 0, x_\epsilon)\) to \((u, v, x) = (u^*, 0, x^*)\). In the case \( p = 1 \), \( Q_0 \) is the point \((u, v, x) = (u_\epsilon, 0, x_\epsilon)\); \( R_0 \) is the point \( u_\epsilon \) in \( u \)-space; \( R^*_0 \) is an interval around \( u^* \) in \( u \)-space. If in addition \( n = 1 \), \( Q^*_0 \) and \( U^*_0 \) coincide.

For a small \( \delta > 0 \), let
\[
U_\epsilon = \{(u, v, x) : |u - u_\epsilon| < \delta, v = 0, |x - x_\epsilon| < \delta\},
\]
\[
U^* = \{(u, v, x) : |u - u^*| < \delta, v = 0, |x - x^*| < \delta\}.
\]

For the system (1.6)–(1.8) with \( \epsilon = 0 \), \( U_\epsilon \) and \( U^* \) are normally hyperbolic manifolds of equilibria of dimension \( n + 1 \). For \( U_\epsilon \), the stable and unstable manifolds of each point have dimensions \( k \) and \( l + 1 \) respectively; for \( U^* \), the stable and unstable manifolds of each point have dimensions \( k + 1 \) and \( l \) respectively. In fact, for the system (1.6)–(1.8) with any fixed \( \epsilon \), \( U_\epsilon \) and \( U^* \) are normally hyperbolic invariant manifolds. The stable and unstable fibers of points have the dimensions just given.

For each \( u_0 \in U_\epsilon \) let \( I_{u_0} = \{(u, 0, x) \in U_\epsilon : u = u_0\} \).

For each \( \epsilon \geq 0 \), let \( M_\epsilon \) be a \( C^{r+11} \) submanifold of \( uvx \)-space of dimension \( l + p \), \( 1 \leq p \leq n \). Assume
(R4) $M = \{(u, v, x, \epsilon) : (u, v, x) \in M_{\epsilon}\}$ is itself a $C^{r+11}$ manifold.

(R5) $M_0$ is transverse to $W_0^s(U_\epsilon)$ at a point in the stable fiber of $(u_\epsilon, 0, x_\epsilon)$.

(R6) The tangent space to $M_0$ at this point contains no nonzero vectors that are tangent to the stable manifold of $I_{u_\epsilon}$.

Each $M_{\epsilon}$ meets $W_\epsilon^s(U_\epsilon)$ transversally in a manifold $S_{\epsilon}$ of dimension $p - 1$. $S_{\epsilon}$ projects along the stable fibers of points to a submanifold $Q_{\epsilon}$ of $ux$-space of dimension $p - 1$. The coordinate system in which the projection is done is $C^1$ projects to a $C^1$ manifold. The proof goes as follows.

Let $\Delta$ be a small neighborhood of $(u^*, 0, x^*)$ in $W_0^u(Q_0^*)$. Then for $\epsilon_0 > 0$ sufficiently small there is a $C^r$ function $\tilde{w} : \Delta \times [0, \epsilon_0) \to \Lambda$ such that:

1. $\tilde{w} = 0$ when $\epsilon = 0$.
2. For $0 < \epsilon < \epsilon_0$, the set of $(u, v, x)$ in the graph of $\tilde{w}(-, \epsilon)$ is contained in $M_{\epsilon}^*$.

We shall use the General Exchange Lemma from [21] to prove Theorem 3.1. In outline, the proof goes as follows.

For each $\epsilon$ the portion of $(n + 1)$-dimensional $ux$-space with $u \in U$ and $x$ near $\lambda(u)$ lies in a normally hyperbolic invariant manifold $K_{\epsilon}$ of dimension $n + 2$. $M_{\epsilon} \cap W^s(K_{\epsilon})$ projects along stable fibers to a $p$-dimensional submanifold $P_{\epsilon}$ of $K_{\epsilon}$. We must trace the evolution of the sets $P_{\epsilon}$, which under the flow of (1.6)–(1.8), become submanifolds $P_{\epsilon}^*$ of $K_{\epsilon}$ of dimension $p + 1$. Let $K = \{(u, v, x, \epsilon) : (u, v, x) \in K_{\epsilon}\}$. In order to study the $P_{\epsilon}^*$, we blow up the surface $v = 0$, $x = \lambda(u)$, $\epsilon = 0$ within the manifold $K$. Once we know where the $P_{\epsilon}^*$ lie for $(u, v, x)$ near $(u^*, 0, x^*)$, we can verify the hypotheses of the General Exchange Lemma.

In Section 4 we define convenient coordinates for doing the calculations. We do the blow-up in Section 5, track the manifolds $P_{\epsilon}^*$ in Section 6, and verify the hypotheses of the General Exchange Lemma in Section 7. This requires replacing the manifolds $P_{\epsilon}$ by different cross-sections of $P_{\epsilon}^*$.

### 4. New Coordinates

Let $\chi(w_2, \ldots, w_n, \epsilon)$ be a $C^{r+10}$ function that parameterizes an $\epsilon$-dependent cross-section to the flow of $\dot{u} = r(u)$ near $u_\epsilon$, such that $\chi(0, \ldots, 0) = u_\epsilon$ and $\chi(w_2, \ldots, w_p, 0, \ldots, 0, \epsilon)$ is a parameterization of $Q_{\epsilon}$. Let

\[ u(w, \epsilon) = u(w_1, \ldots, w_n, \epsilon) = \phi(w_1, \chi(w_2, \ldots, w_n, \epsilon)), \quad v = D_w u(w, \epsilon) z, \quad x = \lambda(u(w, \epsilon)) + \sigma. \]
Writing \((1.6)\)–\((1.8)\) in the new variables \((w, z, \sigma)\), we obtain the system

\[
\begin{align*}
\dot{w} &= z, \\
\dot{z} &= (B(w, \epsilon) - \sigma I)z + C(w, \epsilon)(z, z), \\
\dot{\sigma} &= \epsilon - E(w, \epsilon)z,
\end{align*}
\]

with

\[
\begin{align*}
B(w, \epsilon) &= (D_wu(w, \epsilon))^{-1}(A(u(w, \epsilon)) - \lambda(u(w, \epsilon))I)D_wu(w, \epsilon), \\
C(w, \epsilon) &= (D_wu(w, \epsilon))^{-1}D_w^2u(w, \epsilon), \\
E(w, \epsilon) &= D_w(\lambda \circ u)(w, \epsilon).
\end{align*}
\]

The functions \(B(w, \epsilon), E(w, \epsilon), \) and \(C(w, \epsilon)(z, z)\) are \(C^{\tau+9}\). We choose an open set \(W\) in \(w\)-space such that for \(w \in W\) and small \(\epsilon, u(w, \epsilon) \in U\). Recalling the choice of \(t^*\) in Section 3, we see that we may assume that \(W\) contains \(\{w : 0 \leq w_1 \leq t^* \text{ and } w_2 = \ldots = w_n = 0\}\). We shall consider \((4.1)\)–\((4.3)\) on \(\{(w, z, \sigma, \epsilon) : w \in W, |\sigma| < \beta_0, \text{ and } \epsilon \text{ small}\}\). Let \(\sigma_* = \lambda(u_*) - x_*\) and \(\sigma^* = x^* - \lambda(u^*)\). We have

\[-\beta_0 < -\sigma_* < 0 < \sigma^* < \beta_0.\]

Let \(e_1 = (1, 0, \ldots, 0) \in \mathbb{R}^n\). Notice that for \(w \in W\) and \(\epsilon\) small,

(R3\(w\)) \(B(w, \epsilon)\) has a simple real eigenvalue 0 with eigenvector \(e_1\).

(R3\(w\)) \(B(w, \epsilon)\) has \(k\) eigenvalues with real part less than \(\tilde{\lambda} < 0\) and \(l\) eigenvalues with real part greater than \(\tilde{\mu} > 0\).

(R3\(w\)) \(E(w, \epsilon)e_1 = 1\).

For the system \((4.1)\)–\((4.3)\) with \(\epsilon = 0\), \(w\sigma\) space consists of equilibria. The linearization of \((4.1)\)–\((4.3)\) at one of these equilibria has the matrix

\[
\begin{pmatrix}
0 & I \\
0 & B(w, 0) - \sigma I \\
0 & -E(w, 0)
\end{pmatrix}
\]

For \(w \in W\) and \(\sigma = 0\), this matrix has:

- An eigenvalue 0 with algebraic multiplicity \(n + 2\). The generalized eigenspace is \(wz_1\sigma\)-space.
- \(k\) eigenvalues with real part less than \(\tilde{\lambda} < 0\) and \(l\) eigenvalues with real part greater than \(\tilde{\mu} > 0\).

For \(w \in W\) and \(\sigma \neq 0\), one of the zero eigenvalues becomes \(-\sigma\). For \(w \in W\) and \(|\sigma| < \beta_0\), the matrix has:

- \(n + 2\) eigenvalues with real part between \(-\beta_0\) and \(\beta_0\), at least \(n + 1\) of which are 0, having total algebraic multiplicity \(n + 2\). The sum of their generalized eigenspaces is \(wz_1\sigma\)-space.
- \(k\) eigenvalues with real part less than \(\tilde{\lambda} + \beta_0 < 0\) and \(l\) eigenvalues with real part greater than \(\tilde{\mu} - \beta_0 > 0\).

The system \((4.1)\)–\((4.3)\) has, for each small \(\epsilon\), a normally hyperbolic invariant manifold \(K_\epsilon\) of dimension \(n + 2\) that contains the \((n + 1)\)-dimensional set \(\{(w, z, \sigma) : w \in W, z = 0, \text{ and } |\sigma| < \beta_0\}\), which is locally invariant for every \(\epsilon\). Let \(K = \{(w, z, \sigma) : (w, z, \sigma) \in K_\epsilon\}\).
Lemma 4.1. \( K \) is a \( C^{r+10} \) normally hyperbolic submanifold of \( wz\sigma\epsilon \)-space. It has stable fibers of dimension \( k \) and unstable fibers of dimension \( l \). Both are \( C^{r+10} \) and vary in a \( C^{r+10} \) fashion with the base point.

Proof. \( K \) is also a normally hyperbolic invariant manifold for the \( C^{r+11} \) system (1.6)–(1.8). By [6] it is \( C^{r+11} \) in the \( wz\epsilon \)-variables, and has stable and unstable fibers that are \( C^{r+11} \) and vary in a \( C^{r+10} \) fashion with the base point. Applying the \( C^{r+10} \) coordinate change to the \( wz\epsilon \)-variables, we get the result.

Let \( \tilde{z} = (z_2, \ldots, z_n) \). \( K_0 \) has the form \( \tilde{z} = g(w, z_1, \sigma, \epsilon) \), with \( g C^{r+10} \) by Lemma 4.1. We must have \( g(w, 0, \sigma, \epsilon) = 0 \), so

\[
\tilde{z} = z_1 h(w, z_1, \sigma, \epsilon)
\]

with \( h C^{r+9} \). \( K_0 \) must be tangent at each point of \( w\sigma \)-space to \( wz_1\sigma \)-space. Therefore \( h(w, 0, \sigma, 0) = 0 \), so

\[
h(w, z_1, \sigma, \epsilon) = z_1 h_1(w, z_1, \sigma, \epsilon) + \epsilon h_2(w, z_1, \sigma, \epsilon)
\]

with \( h_1 \) and \( h_2 \) \( C^{r+8} \).

On \( K \) the system (4.1)–(4.3) reduces to the \( C^{r+9} \) system.

\[
\begin{align*}
\dot{w} &= z_1(1, h), \\
\dot{z}_1 &= B_1(w, \epsilon)z_1(0, h) - \sigma z_1 + C_1(w, \epsilon)z_1^2((1, h), (1, h)), \\
\dot{\sigma} &= \epsilon - z_1(1 + E(w, \epsilon)(0, h)).
\end{align*}
\]

We append the equation

\[
\dot{\epsilon} = 0.
\]

In (4.8) and (4.9) we have used

\[
\begin{align*}
B_1(w, \epsilon)(1, h) &= B_1(w, \epsilon)(1, 0) + B_1(w, \epsilon)(0, h) = 0 + B_1(w, \epsilon)(0, h) = B_1(w, \epsilon)(0, h), \\
E(w, \epsilon)(1, h) &= E(w, \epsilon)(1, 0) + E(w, \epsilon)(0, h) = 1 + E(w, \epsilon)(0, h).
\end{align*}
\]

5. Blow-up

As in [23], in \( wz_1\sigma\epsilon \)-space we shall blow up \( w \)-space, which consists of equilibria that are not normally hyperbolic within \( wz_1\sigma \)-space for (4.7)–(4.9) with \( \epsilon = 0 \), to the product of \( w \)-space with a 2-sphere. The 2-sphere is a blow-up of the origin in \( z_1\sigma\epsilon \)-space.

The blowup transformation is a map from \( \mathbb{R}^n \times S^2 \times [0, \infty) \) to \( wz_1\sigma\epsilon \)-space defined as follows. Let \( (w, (\tilde{z}_1, \tilde{\sigma}, \tilde{\epsilon}), \tilde{r}) \) be a point of \( \mathbb{R}^n \times S^2 \times [0, \infty) \); we have \( \tilde{z}_1^2 + \tilde{\sigma}^2 + \tilde{\epsilon}^2 = 1 \). Then the blow-up transformation is

\[
\begin{align*}
w &= w, \\
z_1 &= \tilde{r}^2 \tilde{z}_1, \\
\sigma &= \tilde{r} \tilde{\sigma}, \\
\epsilon &= \tilde{r}^2 \tilde{\epsilon}.
\end{align*}
\]

Under this transformation the system (4.7)–(4.10) becomes one for which the manifold \( \tilde{r} = 0 \) consists entirely of equilibria. The system we shall study is this one divided by \( \tilde{r} \). Division by \( \tilde{r} \) desingularizes the system on the manifold \( \tilde{r} = 0 \) but leaves it invariant.

Note that from (4.6),

\[
h(w, z_1, \sigma, \epsilon) = \tilde{r}^2 h(w, \tilde{z}_1, \tilde{\sigma}, \tilde{\epsilon}, \tilde{r}),
\]

where \( h(w, z_1, \sigma, \epsilon) \) is a \( C^{r+10} \) function.

RAREF ACTIONS IN THE DAFERMOS REGULARIZATION 13
with \( \hat{h} \) \( C^{r+8} \).

We shall need three charts.

5.0.1. Chart for \( \bar{\sigma} < 0 \). This chart uses the coordinates \( w, \bar{z}_a = \frac{z_a}{\bar{\sigma}}, r_a = -\bar{r}\bar{\sigma}, \) and \( \epsilon_a = \frac{\bar{\epsilon}_a}{\bar{\sigma}} \) on the set of points in \( \mathbb{R}^n \times S^2 \times [0, \infty) \) with \( \bar{\sigma} < 0 \). Thus we have

\[
\begin{align*}
\bar{w} &= w, \\
\bar{z}_1 &= r_a^2 \bar{z}_a, \\
\bar{\sigma} &= -r_a, \\
\bar{\epsilon} &= r_a^2 \epsilon_a,
\end{align*}
\]

with \( r_a > 0 \). After division by \( r_a \) (equivalent to division by \( \bar{r} \) up to multiplication by a positive function), the system (4.7)–(4.10) becomes the \( C^{r+8} \) system

\[
\begin{align*}
\dot{w} &= r_a \bar{z}_a(1, r_a^2 \bar{h}), \\
\dot{z}_a &= z_a(1 + r_a B_1(w, r_a^2 \epsilon_a)(0, \bar{h}) + r_a z_a C_1(w, r_a^2 \epsilon_a)(1, r_a^2 \bar{h}))(1, r_a^2 \bar{h}), \\
\dot{r}_a &= r_a(z_a - \epsilon_a + r_a^2 z_a E(w, r_a^2 \epsilon_a)(0, \bar{h})), \\
\dot{\epsilon}_a &= 2\epsilon_a(\epsilon_a - z_a - r_a^2 z_a E(w, r_a^2 \epsilon_a)(0, \bar{h})).
\end{align*}
\]

We consider the system (5.10)–(5.13) with \( r_a \geq 0 \). We have the following structures:

(1) Codimension-one invariant sets: (1) \( z_a = 0 \), (2) \( r_a = 0 \), (3) \( \epsilon_a = 0 \), (4) \( r_a^2 \epsilon_a = k \).

(2) Invariant foliations:

(a) Of \( z_a = 0 \): each plane \( w = w_0 \) is invariant.

(b) Of \( r_a = 0 \): each plane \( w = w_0 \) is invariant.

(3) Equilibria: (1) \( z_a = \epsilon_a = 0 \); (2) \( z_a = \frac{1}{2}, r_a = \epsilon_a = 0 \).

The flow in one of the invariant planes \( r_a = 0, w = w_0 \) is pictured in Figure 5.1. In this figure, the lines \( z_a = 0 \) and \( \epsilon_a = 0 \) are invariant. There are a hyperbolic attractor at \((z_a, \epsilon) = (\frac{1}{2}, 0)\) and a nonhyperbolic equilibrium at the origin. The latter’s unstable manifold is the line \( \epsilon_a = 0 \), and one center manifold is the line \( z_a = 0 \). The origin is quadratically repelling on the portion of this line with \( \epsilon_a > 0 \).

\[\text{Figure 5.1. Flow of (5.10)–(5.13) in the invariant plane } r_a = 0, w = w_0.\]
5.0.2. Chart for $\bar{\epsilon} > 0$. This chart uses the coordinates $w, z_b = \frac{z}{\sqrt{\bar{\epsilon}}}$, $\sigma_b = \frac{\sigma}{\sqrt{\bar{\epsilon}}}$ and $r_b = \bar{r}\sqrt{\bar{\epsilon}}$ on the set of points in $\mathbb{R}^n \times S^2 \times [0, \infty)$ with $\bar{\epsilon} > 0$. Thus we have

\begin{align*}
w &= w, \quad (5.14) \\
z_1 &= r_b^2 z_b, \quad (5.15) \\
\sigma &= r_b \sigma_b, \quad (5.16) \\
\epsilon &= r_b^2, \quad (5.17)
\end{align*}

with $r_b > 0$. After division by $r_b$ (equivalent to division by $\bar{r}$ up to multiplication by a positive function), the system (4.7)–(4.10) becomes the $C^{r+s}$ system

\begin{align*}
\dot{w} &= r_b z_b(1, r_b^2 \tilde{h}), \quad (5.18) \\
\dot{z}_b &= r_b z_b B_1(w, r_b^2)(0, \tilde{h}) - \sigma_b z_b + r_b z_b^2 C_1(w, r_b^2)(1, r_b^2 \tilde{h})(1, r_b^2 \tilde{h}), \quad (5.19) \\
\dot{\sigma}_b &= 1 - z_b - r_b^2 z_b E(w, r_b^2)(0, \tilde{h}), \quad (5.20) \\
\dot{r}_b &= 0. \quad (5.21)
\end{align*}

We consider the system (5.18)–(5.21) with $r_b \geq 0$. We have the following structures:

1. Codimension-one invariant sets: (1) $z_b = 0$, (2) $r_b = r_b^0$.
2. Invariant foliations:
   (a) Of $z_b = 0$: each plane $w = w^0$ is invariant.
   (b) Of $r_b = 0$: each plane $w = w^0$ is invariant.
3. Equilibria: $z_b = 1$, $\sigma_b = r_b = 0$.

The flow in one of the invariant planes $r_b = 0$, $w = w^0$ is pictured in Figure 5.2. In this figure, the line $z_b = 0$ is invariant, and there is a hyperbolic saddle at $(z_b, \sigma_b) = (1, 0)$.

\begin{center}
\includegraphics[width=0.5\textwidth]{chart.png}
\end{center}

**Figure 5.2.** Chart for $\bar{\epsilon} > 0$. Flow of (5.18)–(5.21) in the invariant plane $r_b = 0, w = w^0$.  

5.0.3. Chart for $\bar{\sigma} > 0$. This chart uses the coordinates $w$, $z_c = \frac{z}{\bar{\sigma}^2}$, $r_c = \bar{r}\bar{\sigma}$, and $\epsilon_c = \frac{\epsilon}{\bar{\sigma}^2}$ on the set of points in $\mathbb{R}^n \times S^2 \times [0, \infty)$ with $\bar{\sigma} > 0$. Thus we have

$$w = w$$ (5.22)
$$z_1 = r_c^2 z_c$$ (5.23)
$$\sigma = r_c$$ (5.24)
$$\epsilon = r_c^2 \epsilon_c$$ (5.25)

with $r_c > 0$. After division by $r_c$ (equivalent to division by $\bar{r}$ up to multiplication by a positive function), the system (4.7)–(4.10) becomes the $C^{r+8}$ system

$$\dot{w} = r_c z_c (1, r_c^2 \tilde{h}),$$ (5.26)
$$\dot{z}_c = z_c (-1 + r_c B_1(w, r_c^2 \epsilon_c)(0, \tilde{h}) + r_c z_c C_1(w, r_c^2 \epsilon_c)(1, r_c^2 \tilde{h})) - 2(\epsilon_c - z_c - r_c^2 z_c E(w, r_c^2 \epsilon_c)(0, \tilde{h})),$$ (5.27)
$$\dot{r}_c = r_c (\epsilon_c - z_c - r_c^2 z_c E(w, r_c^2 \epsilon_c)(0, \tilde{h})),$$ (5.28)
$$\dot{\epsilon}_c = 2 \epsilon_c (-\epsilon_c + z_c + r_c^2 z_c E(w, r_c^2 \epsilon_c)(0, \tilde{h})).$$ (5.29)

We consider the system (5.26)–(5.29) with $r_c \geq 0$. The description of the flow is similar to that for the chart for $\bar{\sigma} < 0$. Again, within the space $r_c = 0$, each plane $w = w^0$ is invariant. For a fixed $w^0$, the flow in this plane is pictured in Figure 5.3. This time there are a hyperbolic repeller at $(z_c, \epsilon) = (\frac{1}{2}, 0)$ and a nonhyperbolic equilibrium at the origin. The latter’s stable manifold is the line $\epsilon_c = 0$, and one center manifold is the line $z_c = 0$. The origin is quadratically attracting on the portion of this line with $\epsilon_c > 0$.

![Figure 5.3. Flow of (5.26)–(5.29) in the invariant plane $r_c = 0$, $w = w^0$.](image)

5.0.4. Summary. Figure 5.4 shows the flow in the portion of blow-up space with $\bar{\epsilon} \geq 0$, as reconstructed from these coordinate charts and the corresponding ones for $\bar{z}_1 < 0$ and $\bar{z}_1 > 0$. A value $w = w^0$ is fixed; in the figure we look straight down the $\epsilon$-axis. We see the top of the sphere $w = w^0$, $\bar{r} = 0$, and, outside it, the plane $w = w^0$, $\epsilon = 0$, in which the origin has been blown up to a circle. There are equilibria along the $\sigma$-axis, and two equilibria elsewhere on the circle. The figure shows as dashed curves stable and unstable manifolds of these equilibria; artistic license is taken, since they do not lie in $w = w^0$. 
We consider the $p$-dimensional submanifolds $P_\epsilon$ of $K_\epsilon$ defined at the end of Section 3. In $wz_1\sigma$-coordinates on $K_\epsilon$, $P_\epsilon$ is given by equations of the form
\[
w_i = \hat{w}_i(w_2, \ldots, w_p, z_1, \epsilon), \quad i = 1, p + 1, \ldots, n,
\]
\[
\sigma = -\hat{\sigma}(w_2, \ldots, w_p, z_1, \epsilon),
\]
with $\hat{w}^i$ and $\hat{\sigma}$ $C^{r+10}$ by Lemma 4.1; $\hat{w}^i = 0$ if $z_1 = 0$, and $\hat{\sigma}(0, \ldots, 0, 0, 0) = \sigma_* > 0$. The sets $Q_\epsilon$ defined in Section 3 are given by the same equations with $z_1 = 0$.

6. Tracking

6.1. $P_\epsilon^*$ approaches the unstable manifold of $w_2 \ldots w_p$-space. Let $\delta > 0$ be small. Within $wz_1\sigma$ space, $\{(w, z_1, \sigma) : w \in W, z_1 = 0, -\beta_0 < \sigma < -\frac{1}{2}\delta\}$ is, for each $\epsilon$, a normally hyperbolic (repelling) invariant manifold. Therefore, as long as $\sigma < -\frac{1}{2}\delta$, we can follow the evolution of the $P_\epsilon$ using the usual Exchange Lemma. After a $C^{r+8}$ coordinate change, the $C^{r+9}$ system (4.7)–(4.9) becomes a $C^{r+7}$ system in which stable fibers are lines. We obtain the following result.

**Proposition 6.1.** Let
\[
A = \{(w_2, \ldots, w_p, z_1, \sigma) : \max(|w_2|, \ldots, |w_p|, |z_1|) < \delta \text{ and } -3\delta < \sigma < -\frac{1}{2}\delta\}.
\]

For $\epsilon_0 > 0$ sufficiently small, there is a $C^{r+6}$ function $(\hat{w}_1, \hat{w}_{p+1}, \ldots, \hat{w}_n) : A \times [0, \epsilon_0) \to \mathbb{R}^{n-p+1}$ such that:

1. If $z_1 = 0$, then $(\hat{w}_1, \hat{w}_{p+1}, \ldots, \hat{w}_n) = 0$.
2. For $\epsilon = 0$, the unstable manifold of the subset of $w\sigma$ space given by $\max(|w_2|, \ldots, |w_p|) < \delta$, $w_1 = w_{p+1} = \ldots = w_n = 0$, and $-3\delta < \sigma < -\frac{1}{2}\delta$ has the equations $(w_1, w_{p+1}, \ldots, w_n) = (\hat{w}_1, \hat{w}_{p+1}, \ldots, \hat{w}_n)(w_2, \ldots, w_p, z_1, \sigma, 0)$.
3. For $0 < \epsilon < \epsilon_0$, $\{(w, z_1, \sigma) : (w_2, \ldots, w_p, z_1, \sigma) \in A \text{ and } (w_1, w_{p+1}, \ldots, w_n) = (\hat{w}_1, \hat{w}_{p+1}, \ldots, \hat{w}_n)(w_2, \ldots, w_p, z_1, \sigma, \epsilon)\}$ is contained in $P_\epsilon^*$.

Let $P^*$ denote $\{(w, z^1, \sigma, \epsilon) : \epsilon > 0 \text{ and } (w, z^1, \sigma) \in P_\epsilon^*\}$, together with the limit points of this set that have $\epsilon = 0$. Proposition 6.1 describes $P^*$ for $-3\delta < \sigma < -\frac{1}{2}\delta$. We shall use our blow-up to track $P^*$ as $\sigma$ increases further; we shall denote the pre-image of $P^*$ under the blow-up transformation, as well as the corresponding set in a local coordinate system, by $P^*$ as well.
6.2. $P^*_\epsilon$ arrives at the blow-up cylinder. In $wz_a r_a e_a$-coordinates, the equations for $P^*$ become

$$w_i = \bar{w}_i(w_2, \ldots, w_p, r_a^2 z_a, -r_a, r_a^2 e_a), \quad i = 1, p + 1, \ldots, n,$$

$$\max(|w_2|, \ldots, |w_p|, |r_a^2 z_a|) < \delta, \quad \frac{1}{2} \delta < r_a < 3 \delta, \quad 0 \leq r_a^2 e_a < \epsilon_0.$$ 

Equations for $P^*_\epsilon$ are obtained by setting $r_a^2 e_a = \epsilon$.

The following proposition describes $P^*$ as it arrives at $r_a=0$. See Figure 6.1.

**Proposition 6.2.** Let

$$B = \{(w_2, \ldots, w_p, z_a, r_a, e_a) : \max(|w_2|, \ldots, |w_p|, |z_a|) < \delta, 0 \leq r_a < 3 \delta, 0 \leq e_a < \delta\}.$$ 

For $\delta > 0$ sufficiently small, there is a $C^{r+5}$ function $(\bar{w}_1, \bar{w}_{p+1}, \ldots, \bar{w}_n) : B \to \mathbb{R}^{n-p+1}$ such that:

1. If $z_a = 0$ or $r_a = 0$, then $(\bar{w}_1, \bar{w}_{p+1}, \ldots, \bar{w}_n) = 0$.
2. $\{(w, z_a, r_a, e_a) : (w_2, \ldots, w_p, z_a, r_a, e_a) \in A \text{ and } (w_1, w_{p+1}, \ldots, w_n) = (\bar{w}_1, \bar{w}_{p+1}, \ldots, \bar{w}_n)(w_2, \ldots, w_p, z_a, r_a, e_a)\}$ is contained in $P^*$.

![Figure 6.1](image_url)  

**Figure 6.1.** $P^*_\epsilon$ in the coordinate chart for $\bar{\sigma} < 0$, with $w$ suppressed. The cross-section of $P^*$ defined by (6.6)–(6.7) is shaded.

**Proof.** In $wz_a r_a e_a$-space, we consider the $C^{r+8}$ system (5.10)–(5.13). For $\delta > 0$ small, the codimension-one set

$$\{(w, z_a, r_a, e_a) : \max|w_i| < \delta, z_a = 0, 0 \leq r_a < 3 \delta, \text{ and } 0 \leq e_a < \delta\}$$

is normally hyperbolic (repelling).
The unstable fibers of points in $z_a = 0$ are curves. After a coordinate change of class $C^{r+7}$, we obtain new coordinates $(\hat{w}, z_a, \hat{r}_a, \hat{\epsilon}_a)$, with

$$\hat{w} = w + r_a z_a \hat{W}, \hat{r}_a = r_a (1 + z_a \hat{R}), \hat{\epsilon}_a = \epsilon_a (1 + z_a \hat{E}),$$

in which unstable fibers are lines $(\hat{w}, \hat{r}_a, \hat{\epsilon}_a) = \text{constant}$.

To simplify the notation, we drop the hats in the new coordinates. In the new coordinates, the system becomes

$$\dot{w} = 0,$$  

$$\dot{z}_a = z_a a(w, z_a, r_a, \epsilon_a),$$  

$$\dot{r}_a = -r_a \epsilon_a,$$  

$$\dot{\epsilon}_a = 2 \epsilon_a^2$$

It is of class $C^{r+6}$. Moreover, there is a number $\nu_0 > 0$ such that $a(w, z_a, r_a, \epsilon_a) > \nu_0$.

We shall follow the evolution of a cross-section of $P^*$ parameterized by $(w_2, \ldots, w_p, z_a, \epsilon_a)$; the equations of the cross-section have the form

$$w_i = \hat{w}_i(w_2, \ldots, w_p, z_a, \epsilon_a),$$

$$\dot{w}_i(w_2, \ldots, w_p, 0, \epsilon_a) = \hat{w}_i(w_2, \ldots, w_p, z_a, 0) = 0, \quad i = 1, p + 1, \ldots, n;$$

$$r_a = 2 \delta;$$

from Proposition 6.1, the functions $\hat{w}_i$ are $C^{r+6}$.

We denote the solution of (6.2)–(6.5) whose value at $t = \tau$ is $(w^1, z^1_a, r^1_a, \epsilon^1_a)$ by

$$(w, z_a, r_a, \epsilon_a)(t, \tau, w^1, z^1_a, r^1_a, \epsilon^1_a),$$

a $C^{r+6}$ function. This is the solution of a Silnikov problem of the second type, so Deng’s lemma (Theorem 2.2 of [20]) applies.

One easily calculates that for $\tau = \frac{1}{2} (4(\delta \epsilon_a)^2 - 1)$, $r_a(0, \tau, w^1, z^1_a, r^1_a, \epsilon^1_a) = \delta$.

Given $(w^1_2, \ldots, w^1_p, z^1_a, r^1_a, \epsilon^1_a)$, we wish to find $(w^1, w^1_{p+1}, \ldots, w^1_n)$ such that for $i = 1, p + 1, \ldots, n$,

$$w^1_i - \hat{w}_i(w^1_2, \ldots, w^1_p, z_a(0, \frac{1}{2} (4(\delta \epsilon_a)^2 - 1)), w^1, z^1_a, \epsilon^1_a) = 0.$$  

(6.8)

The desired function is then $(\tilde{w}_1, \tilde{w}_{p+1}, \ldots, \tilde{w}_n) = (w^1_1, w^1_{p+1}, \ldots, w^1_n)$.

For $i = 1, p + 1, \ldots, n$, we define

$$G_i((w^1_1, w^1_{p+1}, \ldots, w^1_n), (w^1_2, \ldots, w^1_p, r^1_a, \epsilon^1_a), z^1_a)$$

to be the left-hand side of (6.8). $G_i$ is a component of a $C^{r+6}$ map $G$ into $\mathbb{R}^{n-p+1}$. The domain of $G$ is $X \times Y \times Z$,

$$X = \{(w^1_1, w^1_{p+1}, \ldots, w^1_n) : \max |w^1_i| < \delta\},$$

$$Y = \{(w^1_2, \ldots, w^1_p, r^1_a, \epsilon^1_a) : \max |w^1_i| < \delta, 0 < r^1_a < \delta, 0 < \epsilon^1_a < \delta\},$$

$$Z = \{z^1_a : |z^1_a| < \delta\}.$$

The proof then proceeds in the following steps. We omit details; for a similar, but harder, argument, see the proof of the General Exchange Lemma in [21]. Let $0 < (r + 5)\gamma < \nu_0$.

1. $G(0, (w^1_2, \ldots, w^1_p, r^1_a, \epsilon^1_a), 0) = 0,$ and $G(0, (w^1_2, \ldots, w^1_p, r^1_a, \epsilon^1_a), z^1_a)$ is of order $e^{-\nu_0 \tau}, \tau = \frac{1}{2} (4(\delta \epsilon_a)^2 - 1)$. 

Proposition 6.3. Let
\[ 20 \] SCHETTER AND SZMOLYAN
for which:
\[ wz = 0 \text{ for } r^2 \]
\[ a = 0. \] Returning to the original \( wz_a r_a \epsilon_a \)-coordinates, the equations for \( P^* \) have the properties given in the proposition.

6.3. \( P^*_e \) moves along the blow-up cylinder. The transformation from \( wz_b \sigma_b r_b \)-coordinates to \( wz_a r_a \epsilon_a \)-coordinates is given by
\[ w = w, \quad z_a = \frac{z_b}{\sigma_b^2}, \quad r_a = -\sigma_b r_b, \quad \epsilon_a = \frac{1}{\sigma_b}. \]

Using this change of coordinates, Proposition 6.2 yields

**Proposition 6.3.** Let
\[ B = \{(w_2, \ldots, w_p, z_b, \sigma_b, r_b) : |w_i| < \delta \text{ for } i = 2, \ldots, p, \]
\[ -\infty < \sigma_b < -\delta^{-\frac{1}{2}}, |z_b| \leq \delta \sigma_b^2, \text{ and } 0 \leq r_b < -\delta \sigma_b \}. \]

For \( \delta > 0 \) sufficiently small, there is a \( Cr+5 \) function
\[ (\tilde{w}_1, \tilde{w}_{p+1}, \ldots, \tilde{w}_n) : B \to \mathbb{R}^{n-p+1} \]
for which:
\begin{itemize}
  \item[(1)] If \( z_b = 0 \) or \( r_b = 0 \), then \( (\tilde{w}_1, \tilde{w}_{p+1}, \ldots, \tilde{w}_n) = 0. \)
  \item[(2)] \( \{(w, z_b, \sigma_b, r_b) : (w_2, \ldots, w_p, z_b, \sigma_b, r_b) \in B \text{ and } (w_1, w_{p+1}, \ldots, w_n) = (\tilde{w}_1, \tilde{w}_{p+1}, \ldots, \tilde{w}_n)(w_2, \ldots, w_p, z_b, \sigma_b, r_b) \} \) is contained in \( P^* \).
\end{itemize}

We choose a cross-section \( C \) of \( P^* \) with \( \sigma_b = \sigma_b^0 << 0. \) Let \( C_{r_b} = \{(w, z_b, \sigma_b) : (w, z_b, \sigma_b, r_b) \in C \}. \)

Note that from (5.21), \( \dot{r}_b = 0, \) so \( r_b \) can be regarded as a parameter in the \( Cr+8 \) system (5.18)–(5.20). (From (5.17), \( \epsilon = r_b^2 \).) For \( r_b = 0, \) the system (5.18)–(5.20) has the normally hyperbolic manifold of equilibria \( L_0 = \{(w, z_b, \sigma_b) : (z_b, \sigma_b) = (1,0)\}. \) For small \( r_b > 0, L_0 \) perturbs to a normally hyperbolic invariant manifold \( L_{r_b}. \) The stable and unstable manifolds of \( L_{r_b} \) are given by
\[ W^s(L_{r_b}) = \{(w, z_b, \sigma_b) : z_b = z_b^0(w, \sigma_b, r_b)\}, \]
\[ W^u(L_{r_b}) = \{(w, z_b, \sigma_b) : z_b = z_b^0(w, \sigma_b, r_b)\}; \]
the functions $z_b^s$ and $z_b^u$ are $C^{r+8}$. For $r_b = 0$, each point $(w^0, 1, 0)$ of $L_0$ is an equilibrium; its stable fiber is simply its one-dimensional stable manifold, which has the equation $(w, z_b) = (w^0, z_b^s(w^0, \sigma_b, 0))$. The portion of $W^s(L_0)$ in $\sigma_b < 0$ has $0 < z_b < 1$. Therefore, if we choose $\sigma_b^*$ sufficiently negative in defining $C$, the surfaces $C_0$ and $W^s(L_0)$ meet transversally. See Figure 6.2. The intersection projects along the foliation of $W^s(L_0)$ by stable manifolds of points to the submanifold of $L_0$ given by $\{(w, z_b, \sigma_b) : w_1 = w_{p+1} = \ldots = w_n = 0, (z_b, \sigma_b) = (1, 0)\}$.

The flow of (5.18)-(5.20) on $L_{r_b}$ is $\dot{w} = r_b(1, 0) + O(r_b^2)$. For small $r_b > 0$ we follow the solution from $C_{r_b}$ until $w_1$ is close to $t^*$. From the Exchange Lemma for normally hyperbolic manifolds of equilibria (Theorem 2.3 of [21]), we have the following result.

**Proposition 6.4.** Let $\eta > 0$ be small. Let

$$D = \{(w_1, w_2, \ldots, w_p, \sigma_b) : \max(|w_1 - t^*|, |w_2|, \ldots, |w_p|, |\sigma_b|) \leq \eta\}.$$ 

For $r_b^* > 0$ sufficiently small, there is a $C^{r+2}$ function $\tilde{w}_{p+1}, \ldots, \tilde{w}_n, \tilde{\sigma}_b : D \times [0, r_b^*) \to \mathbb{R}^{n+p+1}$ such that:

1. As $r_b \to 0$, $(\tilde{w}_{p+1}, \ldots, \tilde{w}_n)(w_1, w_2, \ldots, w_p, \sigma_b, r_b)$ and $\tilde{z}_b(w_1, w_2, \ldots, w_p, \sigma_b, r_b) - z_b^u(w_1, w_2, \ldots, w_p, 0, \ldots, 0, \sigma_b, r_b)$ approach $0$ exponentially, along with all their partial derivatives of order at most $r$.

2. Let $E_{r_b} = \{(w, z_1, \sigma) : (w_1, w_2, \ldots, w_p, \sigma) \in A$ and $(w_{p+1}, \ldots, w_n, z_b) = (\tilde{w}_{p+1}, \ldots, \tilde{w}_n, \tilde{z}_b)(w_1, w_2, \ldots, w_p, \sigma_b, r_b)\}$. For $0 < r_b < r_b^*$, $E_{r_b}$ is contained in $P_{\epsilon^*}$, $\epsilon = r_b^2$.

See Figure 6.3. Let $E = \{(w, z_b, \sigma_b, r_b) : 0 \leq r_b \leq r_b^* \text{ and } (w, z_b, \sigma_b) \in E_{r_b}\}$.

### 6.4. $P_{\epsilon^*}$ moves down the blow-up cylinder.

The transformation from $w z_b \sigma_b r_b$-coordinates to $w z_c r_c \epsilon_c$-coordinates is given by

$$w = w, \quad z_c = \frac{z_b}{\sigma_b^*}, \quad r_c = \sigma_b r_b, \quad \epsilon_c = \frac{1}{\sigma_b^*}. $$
Figure 6.3. The invariant space \((w_2, \ldots, w_n)\) fixed, \(r_b = 0\) for (5.18)–(5.21).

In \(w_z r_c \epsilon_c\)-coordinates, the two-dimensional face of \(E\) with \(\sigma_b = \eta\) corresponds to

\[
F_{\frac{1}{r'}} = \{(w, z, r_c, \epsilon_c) : \max(|w_1 - t^*|, |w_2|, \ldots, |w_p|) \leq \eta, \ 0 \leq r_c < \eta r^*_b, \ \epsilon_c = \frac{1}{r'^2},
\]

\[
(w_{p+1}, \ldots, w_n) = (w_{p+1}, \ldots, \hat{w}_n)(w_1, w_2, \ldots, w_p, \eta, r_c), \ z_c = \frac{1}{r'^2} \hat{z}_b(w_1, w_2, \ldots, w_p, \eta, r_c)\}.
\]

See Figure 6.4

We follow the flow until \(\epsilon_c = \delta > 0\), arriving at a set \(F_\delta\) of the form

\[
F_\delta = \{w, z, r_c, \epsilon_c) : \max(|w_1 - t^*|, |w_2|, \ldots, |w_p|) \leq \delta, \ 0 \leq r_c < \delta, \ \epsilon_c = \delta,
\]

\[
(w_{p+1}, \ldots, w_n, z_c) = (w^x_{p+1}, \ldots, w^x_n, z^x_c)(w_1, w_2, \ldots, w_p, r_c)\}, \quad (6.9)
\]

where \((w^x_{p+1}, \ldots, w^x_n, z^x_c)\) is \(C^{r+2}\).

6.5. \(P^*_c\) leaves the blow-up cylinder. Finally we follow solutions from \(F_\delta\) until \(r_c\) is close to \(\sigma^*\).

Proposition 6.5. Let \(\delta > 0\) be small. Let

\[
G = \{(w_1, w_2, \ldots, w_p, r_c) : \max(|w_1 - t^*|, |w_2|, \ldots, |w_p|, |r_c - \sigma^*|) < \delta\}.
\]

For \(\epsilon^*_c > 0\) sufficiently small, there is a \(C^{r+2}\) function

\[
(\hat{w}_{p+1}, \ldots, \hat{w}_n, \hat{z}_c) : G \times [0, \epsilon^*_c) \to \mathbb{R}^{n-p+1}
\]

for which:

1. \((\hat{w}_{p+1}, \ldots, \hat{w}_n, \hat{z}_c) = 0\) when \(\epsilon_c = 0\).
Figure 6.4. Flow of (5.26)–(5.29), with \( w \) suppressed. The set of points in \( F_\delta \) with a fixed value of \( (w_1, w_2, \ldots, w_p) \) is a curve. Solutions through points in this curve are shown.

(2) \( \{(w, z_c, r_c, \epsilon_c) : (w_1, w_2, \ldots, w_p, r_c, \epsilon_c) \in G \times [0, \epsilon_c^*] \text{ and } (w_{p+1}, \ldots, w_n, z_c) = (\tilde{w}_{p+1}, \ldots, \tilde{w}_n, \tilde{z}_c)(w_1, w_2, \ldots, w_p, r_c, \epsilon_c)\} \) is contained in \( P^* \).

Proof. In \( wz_c r_c \epsilon_c \)-space, for \( \delta > 0 \) small, the codimension-one set
\[
\{(w, z_c, r_c, \epsilon_c) : |w| < \delta, z_c = 0, 0 \leq r_c \leq \sigma^* + \delta, \text{ and } 0 \leq \epsilon_c < 2\delta\}
\]
is normally hyperbolic (attracting) for the \( C^{r+8} \) system (5.26)–(5.29).

The stable fibers of points in \( z_c = 0 \) are curves. In new \( C^{r+7} \) coordinates \( (\tilde{w}, z_c, \tilde{r}_c, \tilde{\epsilon}_c) \), with
\[
\tilde{w} = w + r_c z_c \tilde{W}, \quad \tilde{r}_c = r_c (1 + z_c \tilde{R}), \quad \tilde{\epsilon}_c = \epsilon_c (1 + z_c \tilde{E}),
\]
they are lines \( (\tilde{w}, \tilde{r}_c, \tilde{\epsilon}_c) = \text{ constant} \).

To simplify the notation, we drop the checks in the new coordinates. In the new coordinates, the system becomes
\[
\begin{align*}
\dot{w} &= 0, \\
\dot{z}_c &= z_c b(w, z_c, r_c, \epsilon_c), \\
\dot{r}_c &= r_c \epsilon_c, \\
\dot{\epsilon}_c &= -2\epsilon_c^2,
\end{align*}
\]
a \( C^{r+6} \) system. Moreover, there is a number \( \omega_0 < 0 \) such that \( b(w, z_c, r_c, \epsilon_c) < \omega_0 \).

We denote the solution of (6.11)–(6.14) whose value at \( t = 0 \) is \( (w_0, z_c^0, r_c^0, \epsilon_c^0) \) by
\[
(w, z_c, r_c, \epsilon_c)(t, 0, w_0^0, z_c^0, r_c^0, \epsilon_c^0),
\]
a $C^{r+6}$ function. This is the solution of an initial value problem, and also of a Silnikov problem of the first type, so Deng’s lemma (Theorem 2.2 of [20]) applies.

We easily calculate that if $\epsilon^0_c = \delta$ and $(r_c, \epsilon_c) = (r^1_c, \epsilon^1_c)$ at time $t$, then $r^0_c = r^1_c \sqrt{\epsilon^1_c / \delta}$ and $t = \frac{\delta - \epsilon^0_c}{2 \epsilon^0_c}$.

To avoid proliferation of notation, we shall use the description (6.9) of $F_\delta$ in the new coordinates.

The desired function $(\bar{w}_{p+1}, \ldots, \bar{w}_n, \bar{z}_e)(w^1_1, w^1_2, \ldots, w^1_p, r^1_c, \epsilon^1_c)$ is as follows. Given $(w^1_1, w^1_2, \ldots, w^1_p, r^1_c, \epsilon^1_c)$, with $\max(|w^1_1 - t^*|, |w^1_2|, \ldots, |w^1_p|, |r^1_c - \sigma^*|) < \delta$ and $0 < \epsilon^1_c < \epsilon^*_c$, where $\epsilon^*_c$ is small, let $\epsilon^0_c = \delta$, $r^0_c = r^1_c \sqrt{\epsilon^1_c / \delta}$ and $t = \frac{\delta - \epsilon^0_c}{2 \epsilon^0_c}$. Then

$$\bar{w}^1_i(w^1_1, w^1_2, \ldots, w^1_p, r^1_c, \epsilon^1_c) = w^1_i(w^1_1, \ldots, w^1_p, r^0_c), \quad i = p + 1, \ldots, n,$$

$$z^1_c(w^1_1, w^1_2, \ldots, w^1_p, r^1_c, \epsilon^1_c) = z_c(t, 0, w^1_1, \ldots, w^1_p, (w^1_p, \ldots, w^1_n, z^1_c)(w^1_1, \ldots, w^1_p, r^0_c, r^0_c, \epsilon^0_c)).$$

The functions $w^1_i$ and $z^1_c$ are of class $C^{r+2}$.

From Proposition 6.4 it follows that in the coordinates we are using, all partial derivatives of $(w^1_{p+1}, \ldots, w^1_n, z^1_c)$ of order $i \leq r + 2$ go to 0 exponentially as $r^0_c \to 0$. Choose $\gamma > 0$ such that $\omega_0 + (r + 5)\gamma < 0$. By Deng’s Lemma, all partial derivatives of $z_c(t, 0, w^0, \epsilon^*_c, r^0_c, \epsilon^0_c)$ of order $i \leq r + 5$ are of order $e^{(w^0 + r)\gamma}$. It follows that as $\epsilon_c \to 0$, $(\bar{w}_{p+1}, \ldots, \bar{w}_n, \bar{z}_e) \to 0$ exponentially, along with its derivatives through order $r + 2$ with respect to all variables. Returning to the original $w, z, r, \epsilon_c$-coordinates, the equations for $P^*$ have the properties given in the proposition.

7. COMPLETION OF THE PROOF

We are now ready to prove Theorem 3.1 by verifying the hypotheses of the General Exchange Lemma from [21].

We have seen that (4.1)–(4.3) has, for each small $\epsilon$, a normally hyperbolic invariant manifold $K_\epsilon$ of dimension $n + 2$ that contains $\{(w, z, \sigma) : w \in W, z = 0, 0 < |\sigma| < \beta_0\}$. Let $\lambda_0 = \tilde{\lambda} + \beta_0 < 0$ and $\mu_0 = \tilde{\mu} - \beta_0 > 0$. For $w \in W$ and $|\sigma| < \beta_0$, the matrix (4.4) has $k$ eigenvalues with real part less than $\lambda_0$, $l$ eigenvalues with real part greater than $\mu_0$, and $n + 2$ real eigenvalues between $-\beta_0$ and $\beta_0$. From (3.1),

$$\lambda_0 + \mu_0 + r\beta_0 = \tilde{\lambda} + \tilde{\mu} + r\beta_0 < 0 < \tilde{\mu} - \max(7, 2r + 2)\beta_0 = \mu_0 - \max(6, 2r + 1)\beta_0. $$

It follows easily that hypotheses (E1) and (E2) of the General Exchange Lemma are satisfied on a neighborhood of $K$ in $wz\sigma\epsilon$-space.

Let $\Sigma$ be a codimension-one submanifold of $wz\sigma\epsilon$-space defined by an equation of the form $\sigma = \sigma(w, z, \epsilon)$, with $\sigma(w, 0, 0) = -\delta$. From (R4)–(R6), for $\epsilon > 0$ we can use the usual Exchange Lemma to follow $M$ until it meets $\Sigma$. Let $\hat{M} = M^* \cap \Sigma, \hat{M}_\epsilon = \{(w, z, \sigma) : (w, z, \sigma, \epsilon) \in \hat{M}\}$. Instead of the manifolds $M_\epsilon$ described by (R4)–(R6), in verifying hypotheses (E3)–(E5) of the General Exchange Lemma, we will use the manifolds $\hat{M}_\epsilon$. Since $M$ is $C^{r+1}$, the usual Exchange Lemma implies that $\hat{M}$ is $C^{r+8}$. Each $\hat{M}_\epsilon$ has dimension $l + p$, and hypotheses (E3)–(E5) of the General Exchange Lemma are satisfied. Since $\hat{M}_0$ is contained in $W^0_0\{((w, z, \sigma) : w^1 = w^{p+1} = \ldots = w^n = 0, z = 0, \sigma \text{ near } -\delta\})$, in hypothesis (E4) we have $x_* = 0$. 
The choice of $\Sigma$ determines the sets $P_i$; the choice of $P$, determines whether a coordinate system on $K$ in which (E6)–(E8) hold can be found. We shall first describe convenient coordinates on $K$ in which $\Sigma$ can be defined. We shall then define coordinates on $K$ in which (E6)–(E8) hold.

On $\{(w, z_1, \sigma, \epsilon) : \max(|w_i|, |z_1|) < \delta, -3\delta < \sigma < -\frac{1}{2}\delta, 0 \leq \epsilon < \delta\}$, we can make a $C^{r+8}$ change of coordinates such that the $C^{r+9}$ system (4.7)–(4.10) becomes

\[\begin{align*}
\dot{w} &= 0, \\
\dot{z}_i &= z_i a(w, z_1, \sigma, \epsilon), \\
\dot{\sigma} &= \epsilon,
\end{align*}\]

a $C^{r+7}$ system with $a(w, z_1, \sigma, \epsilon) > \mu_0 > 0$. In these coordinates, we let $\Sigma$ be defined by $\sigma = -2\delta$. Then a cross-section of $P^*$ is given by

\[\begin{align*}
w_i &= \dot{w}_i(w_2, \ldots, w_p, z_1, \epsilon), \\
\dot{w}_i(w_2, \ldots, w_p, 0, \epsilon) &= 0, \\
\sigma &= -2\delta,
\end{align*}\]

with $\dot{w}_i C^{r+8}$. Let the solution of (7.1)–(7.3) with $(w, z_1, \sigma)(\tau) = (w^1, z_1^1, \sigma^1)$ be $(w, z_1, \sigma)(t, \tau, w^1, z_1^1, \sigma^1, \epsilon)$; the mapping is $C^{r+7}$. Note that $\sigma(0, \frac{\partial^1}{\epsilon}, w^1, z_1^1, \sigma^1, \epsilon) = -2\delta$.

For $-2\delta < \sigma^1 < -\frac{1}{2}\delta$, we define new $C^{r+7}$ coordinates $y_i(w^1, z_1^1, \sigma^1, \epsilon), i = 1, p + 1, \ldots, n$, by

\[y_i(w^1, z_1^1, \sigma^1, \epsilon) = w_i^1 - \dot{w}_i(w_2^1, \ldots, w_p^1, z_1^0(0, \frac{\sigma^1 + 2\delta}{\epsilon}, w^1, z_1^1, \sigma^1, \epsilon), \epsilon), \quad i = 1, p + 1, \ldots, n.\]

**Proposition 7.1.** $y_i - (w_i^1 - \dot{w}_i(w_2^1, \ldots, w_p^1, 0, \epsilon))$ and its derivatives through order $r + 6$ go to 0 exponentially as $\epsilon \to 0$. If we use $(y_1, w_2, \ldots, w_p, y_{p+1}, \ldots, y_n, z_1, \sigma, \epsilon)$ as coordinates on $\{(w, z_1, \sigma, \epsilon) : \max(|w_i|, |z_1|) < \delta, -2\delta < \sigma < -\frac{1}{2}\delta, 0 \leq \epsilon < \delta\}$ the system takes the form

\[\begin{align*}
\dot{w}_i &= 0, & i &= 2, \ldots, p, \\
\dot{y}_i &= 0, & i &= 1, p + 1, \ldots, n, \\
\dot{z}_i &= z_i a(w, y, z_1, \sigma, \epsilon), \\
\dot{\sigma} &= \epsilon,
\end{align*}\]

a $C^{r+6}$ system with $a(w, y, z_1, \sigma, \epsilon) > \mu_0 > 0$ and $P^*$ given by $y = 0$.

**Proof.** From its definition, $y_i$ is constant on orbits and equals 0 on $P^*$. Since $y_i$ is constant on orbits, the new system has the form (7.5)–(7.8). By Deng’s lemma (Theorem 2.2 of [20]), for $-2\delta < \sigma < -\frac{1}{2}\delta$, $z_i(0, \frac{\sigma^1 + 2\delta}{\epsilon}, w^1, z_1^1, \sigma^1, \epsilon)$ and its derivatives through order $r + 6$ go to 0 exponentially as $\epsilon \to 0$. Therefore

\[y_i - (w_i^1 - \dot{w}_i(w_2^1, \ldots, w_p^1, 0, \epsilon)) = \dot{w}_i(w_2^1, \ldots, w_p^1, 0, \epsilon) - \dot{w}_i(w_2^1, \ldots, w_p^1, z_1^0(0, \frac{\sigma^1 + 2\delta}{2}, w^1, z_1^1, \sigma^1, \epsilon), \epsilon)\]

and its derivatives through order $r + 6$ go to 0 exponentially as $\epsilon \to 0$. □

In the coordinates $(y_1, w_2, \ldots, w_p, y_{p+1}, \ldots, y_n, z_1, \sigma, \epsilon)$, $\Sigma$ is just the set $\sigma = \delta$, and each $P_\epsilon$, in the coordinates $(y_1, w_2, \ldots, w_p, y_{p+1}, \ldots, y_n, z_1, \sigma)$, is given by $(y_1 = y_{p+1} = \ldots = y_n = 0,$
σ = δ. The coordinates \((u^0, v^0, w^0)\) in which hypotheses (E6)–(E8) of the General Exchange Lemma hold are given by

\[ u^0 = \sigma + \delta, \quad v^0 = (w_2, \ldots, w_p, z_1), \quad w^0 = (y_1, y_{p+1}, \ldots, y_n). \]

In (E7) we use \(a = 1\).

Let \(V^* = \{(w, z_1, \sigma) : \max(|w_1 - t^*|, |w_2|, \ldots, |w_n|, |z_1|, |\sigma - \sigma^*|) < \delta\}\). The coordinate system in which hypothesis (E9) holds is essentially given by Proposition 6.5; \(w^1\) is the \(C^{r+2}\) function \((\tilde{w}_{p+1}, \ldots, \tilde{w}_n, \tilde{z}_0)\). In these \(C^{r+2}\) coordinates, the system is \(C^{r+1}\), so (E10) is satisfied. Since, for the original differential equation, \(\dot{x} = \epsilon\), (E11) is satisfied with \(a = 1\) for \(\delta\) sufficiently small.

Since all hypotheses of the General Exchange Lemma are satisfied, Theorem 3.1 follows.
