WAVENUMBER-EXPLICIT \( H^P \)-BEM FOR HIGH FREQUENCY SCATTERING

MAIKE LÖHNDORF* AND JENS MARKUS MELENK†

Abstract. For the Helmholtz equation (with wavenumber \( k \)) and analytic curves or surfaces \( \Gamma \) we analyze the Galerkin discretization of classical combined field integral equations in an \( L^2 \)-setting. We give abstract conditions on the approximation properties of the ansatz space that ensure stability and quasi-optimality of the Galerkin method. Special attention is paid to the \( hp \)-version of the boundary element method (\( hp \)-BEM). Under the assumption of polynomial growth of the solution operator we show stability and quasi-optimality of the \( hp \)-BEM if the following scale resolution condition is satisfied: the polynomial degree \( p \) is at least \( O(\log k) \) and \( kh/p \) is bounded by a number that is sufficiently small, but independent of \( k \). Under this assumption, the constant in the quasi-optimality estimate is independent of \( k \). Numerical examples in 2D illustrate the theoretical results and even suggest that in many cases quasi-optimality is given under the weaker condition that \( kh/p \) is sufficiently small.

AMS subject classification. 65N38, 65R20, 35J05

1. Introduction. Acoustic and electromagnetic scattering problems are often treated with boundary integral equation methods. In a time-harmonic acoustic setting, popular boundary integral operators (BIOs) are the combined field integral operators, namely, those usually attributed to Burton & Miller, [8] (see (1.5)) and those commonly associated with the names of Brakhage & Werner [3], Leis [12], and Panić [20] (see (1.4)). The present paper is devoted to the study of discretizations of these two combined field BIOs for the case of smooth (more precisely: analytic) geometries paying special attention to the situation of large wavenumbers \( k \).

In the present context of smooth geometries, the combined field operators \( A_k \) and \( A_k' \) are \( L^2(\Gamma) \)-invertible and compact perturbations of the identity. At first glance, therefore, the stability and convergence theory of Galerkin discretizations of the combined field BIEs does not seem to pose difficulties since general functional analytic arguments yield asymptotic quasi-optimality. However, these general arguments give no indication of how the wavenumber \( k \) enters in the estimates and, in particular, affects the onset of quasi-optimal convergence. The recent \( k \)-explicit regularity theory for Helmholtz BIOs developed in [16] allows us be explicit at this point for the \( hp \)-version of the BEM in Corollaries 3.18, 3.21: For analytic geometries and under the assumption that the solution operator for the combined field BIO grows at most polynomially in the wavenumber \( k \), a scale resolution condition of the form

\[
\frac{kh}{p} \text{ sufficiently small } \quad \text{and} \quad p \geq C\log k
\]  

ensures quasi-optimality of the \( hp \)-BEM. We stress that, by [7], the assumption of polynomial growth of the norm of the inverse of the combined field BIO is ensured for star-shaped domains so that the present paper provides a complete \( k \)-explicit convergence theory for the case of star-shaped domains with analytic boundary. It is

*KAPSCH TRAFFICCOM, AM EUROPLATZ 2, A-1120 WIEN
†INSTITUT FÜR ANALYSE UND SCIENTIFIC COMPUTING, TECHNISCHE UNIVERSITÄT WIEN, AUSTRIA (MELENK@TUWIEEN.AC.AT).
worth rephrasing the scale resolution condition (1.1) as follows: If the approximation order $p$ is selected as $p = O(\log k)$, then the onset of quasi-optimality is achieved for $h = O(p/k)$, i.e., for a fixed number of degrees of freedom per wavelength. The numerical results of Section 4 illustrate that indeed a scale resolution condition of the form (1.1) ensures quasi-optimality of the $hp$-BEM. The side condition $p = O(\log k)$ in (1.1) may be viewed as expressing the possibility of “pollution”, i.e., the possibility that the onset of quasi-optimality of the method is $k$-dependent. Nevertheless, our numerical experiments show that the weaker condition “$kh/p$ small” alone is often sufficient for quasi-optimality of the $hp$-BEM. Put differently: in contrast to the finite element method, the BEM does not appear to be very susceptible to “pollution.”

To the authors’ knowledge, the only other $k$-explicit stability analysis for discretizations of combined field BIs is provided in [9], where the special cases of circular or spherical geometries are studied; in that setting the double layer and single layer operators can be diagonalized simultaneously by Fourier techniques, which allows [9] to show that the combined field BIs are even $L^2$-elliptic.

The result of the present paper have counterparts in the context of differential equations and finite elements. Decomposition results analogous to those of [16] have recently been obtained in [17, 18] for several Helmholtz boundary value problems. A $k$-explicit convergence theory for the $hp$-version of the finite element method has also been developed in [17, 18] using similar techniques; also there, the key scale resolution condition on the mesh size $h$ and the approximation order $p$ takes the form (1.1).

The present paper analyzes the classical $hp$-BEM for high frequency scattering problems. This approach mandates a scale resolution condition of the form “$kh/p$ sufficiently small” and thus for problems in $\mathbb{R}^d$, the problem size $N$ will scaling at least like $N = O(k^{d-1})$. To circumvent or mitigate this scale resolution condition, integral equation methods that are based on non-polynomial ansatz spaces have attracted significant attention in recent years; we refer to the survey [4] for an up-to-date account. While these non-standard methods can perform very impressively, their stability is typically not analyzed; a notable exception is the analysis of [9] for the special case of a circular/spherical geometry.

The paper is organized as follows: The remainder of this first section introduces general notation and various boundary integral operators. Section 2 collects the relevant results from [16] and rephrases them in a simplified form suitable for our $L^2$-based analysis. Section 3 shows how the regularity theory of Section 2 permits a $k$-explicit stability and convergence analysis of the $hp$-BEM. We acknowledge here that our technique, which derives the stability of the method from approximation results for suitable adjoint problems, has previously been used in the literature, for example, in [15, 17, 18] and notably [2] in a BEM-context. In Section 4 finally, we present numerical results for the $hp$-BEM in 2D.

1.1. Notation and General Assumptions.

1.1.1. General Notation. Let $\Omega \subset \mathbb{R}^d$, $d \in \{2, 3\}$, be a bounded Lipschitz domain with a connected boundary. Throughout this work we assume that $\Gamma := \partial \Omega$ is analytic. Furthermore, we assume for the case $d = 2$ the scaling condition $\text{diam} \Omega < 1$. We set $\Omega^+ := \mathbb{R}^d \setminus \Omega$. Throughout the paper, we assume that the open ball $B_R := B_R(0)$ of radius $R$ around the origin contains $\overline{\Omega}$, i.e., $\overline{\Omega} \subset B_R$. We set $\Omega_R := (\Omega \cup \Omega^*) \cap B_R = B_R \setminus \Gamma$. We will denote by $\gamma_0^{\text{int}}$ and $\gamma_0^{\text{ext}}$ the interior and exterior trace operator on $\Gamma$. The interior and exterior co-normal derivative operators are denoted by $\gamma_1^{\text{int}}$, $\gamma_1^{\text{ext}}$, i.e., for sufficiently smooth functions $u$, we set $\gamma_1^{\text{int}} u := \gamma_0^{\text{int}} \nabla u \cdot \overline{n}$ and $\gamma_1^{\text{ext}} u := \gamma_0^{\text{ext}} \nabla u \cdot \overline{n}$, where, in both cases $\overline{n}$ is the unit normal
vector point out of $\Omega$. As is standard, we introduce the jump operators

$$[u] = \gamma^{ext}_0 u - \gamma^{int}_0 u, \quad [\partial_n u] = \gamma^{ext}_1 u - \gamma^{int}_1 u.$$  

For linear operators $\tilde{A}$ that map into spaces of piecewise defined functions, we define the operators $[\tilde{A}]$ and $[\partial_n \tilde{A}]$ in an analogous way, e.g., $[\tilde{A}]\varphi = [\tilde{A}\varphi]$. Sobolev spaces $H^s$ are defined in the standard way, [1, 24]. We stress, however, that if an open set $\omega \subset \mathbb{R}^d$ consists of $m \in \mathbb{N}$ components of connectedness $\omega_i$, $i = 1, \ldots, m$, then the space $H^s(\omega_i)$ can be identified with the product space $\prod_{i=1}^m H^s(\omega_i)$. Sets of analytic functions will play a very important role in our theory. We therefore introduce the following definition.

**Definition 1.1.** For an open set $T$ and constant $C_f$, $\gamma_f > 0$ we set

$$\mathfrak{A}(C_f, \gamma_f, T) := \{ f \in L^2(T) \mid \|\nabla^nf\|_{L^2(T)} \leq C_f \gamma_f^n \max\{n + 1, |k|\}^n \quad \forall n \in \mathbb{N}_0\}.$$  

Here, $|\nabla^nu(x)|^2 = \sum_{\alpha \in N^n:|\alpha| = n} \frac{n!}{\alpha!} |D^n u(x)|^2$.

Tubular neighborhoods $T$ of $\Gamma$ are open sets of such that $T \supset \{ x \in \mathbb{R}^d \mid \text{dist}(x, \Gamma) < \varepsilon \}$ for some $\varepsilon > 0$.

Throughout the paper, we will use the following conventions:

**Convention 1.2.**

(i) We assume $|k| \geq k_0 > 0$ for some fixed $k_0 > 0$.

(ii) If the wavenumber $k$ appears outside the boundary integral operators such as $A_k, A_k'$, then it is just a short-hand for $|k|$. In particular, $k$ stands for $|k|$ in estimates. For example, $k \geq k_0$ means $|k| \geq k_0$.

1.1.2. Layer Potentials. In recent years, boundary element methods (BEM) and BIOs have been made accessible to a wider audience through several monographs, e.g., [10, 14, 21, 23]. We refer to these books for more information about the operators studied here.

We denote by $V_k, K_k, K_k'$ the usual single layer, double layer, and adjoint double layer operators for the Helmholtz equation. The single layer and double layer potentials are denoted by $\hat{V}_k$ and $\hat{K}_k$. More specifically, we define the Helmholtz kernel $G_k$ by

$$G_k(x, y) := \begin{cases} \frac{1}{4\pi} H_0^{(1)}(k|x-y|), & d = 2, \\ \frac{1}{4\pi} \ln \frac{|x-y|}{|x-y|}, & d = 3, \end{cases}$$  

for $k > 0$,

$$G_k := \hat{G}_{-k} \quad \text{for } k < 0,$$

where $H_0^{(1)}$ is the first kind Hankel function of order zero. The limiting case $k = 0$ corresponds to the Laplace operator and is defined as $G_0(x, y) = -1/(2\pi) \ln |x-y|$ for the case $d = 2$ and $G_0(x, y) = 1/(4\pi|x-y|)$ for the case $d = 3$. The potential operators $\hat{V}_k$ and $\hat{K}_k$ are defined by

$$(\hat{V}_k \varphi)(x) := \int_G G_k(x, y) \varphi(y) \, ds_y, \quad (\hat{K}_k \varphi)(x) := \int_G \partial_n G_k(x, y) \varphi(y) \, ds_y, \quad x \in \mathbb{R}^d \backslash \Gamma.$$  

From these potentials, the single layer, double layer, and adjoint double layer operators are defined as follows:

$$V_k := \gamma^{int}_0 \hat{V}_k, \quad K_k := \frac{1}{2} \left( \gamma^{int}_0 \hat{K}_k + \gamma^{ext}_0 \hat{K}_k \right), \quad K_k' := \gamma^{int}_1 \hat{V}_k - \frac{1}{2} \text{Id}. \quad (1.2)$$
We mention in passing that for $k \neq 0$, the potentials $\tilde{V}_k$ and $\tilde{K}_k$ are solutions of the homogeneous Helmholtz equation on $\mathbb{R}^d \setminus \Gamma$; for $k > 0$ they satisfy the outgoing Sommerfeld radiation condition while for $k < 0$, they satisfy the incoming radiation condition.

We have for all $k \in \mathbb{R}$ for the $L^2(\Gamma)$ scalar product and all $\varphi, \psi \in H^{1/2}(\Gamma)$:

\begin{align*}
(V_k \varphi, \psi)_{L^2(\Gamma)} &= (\varphi, V_{-k} \psi)_{L^2(\Gamma)}, \\
(K_k \varphi, \psi)_{L^2(\Gamma)} &= (\varphi, K'_{-k} \psi)_{L^2(\Gamma)},
\end{align*}

(1.3a) \quad (1.3b)

i.e., the adjoints of $V_k$ and $K_k$ are $V_{-k}$ and $K'_{-k}$, respectively.

1.1.3. Combined Field Operators. For a coupling parameter $\eta \in \mathbb{R} \setminus \{0\}$ we consider the following two combined field operators

\begin{align*}
A_k &= \frac{1}{2} + K - i\eta V, \\
A'_k &= \frac{1}{2} + K' + i\eta V.
\end{align*}

(1.4) \quad (1.5)

In order to avoid keeping track of the precise dependence of various constants on $\eta$, we assume throughout this paper that

\[ C_0^{-1}|k| \leq |\eta| \leq C_0|k| \]

(1.6)

for some fixed $C_0 > 0$. On smooth surfaces, it is well-known, [6, 8], that the operators $A_k$ and $A'_k$ are invertible as operators acting on $L^2(\Gamma)$. In fact, $A_k$ is invertible as an operator on $H^s(\Gamma)$, $s \geq 0$, and $A'_k$ is invertible as an operator on $H^s(\Gamma)$, $s \geq -1/2$.

In general, little is known about the $k$-dependence of the norms of their inverses. A notable exception are star-shaped geometries, for which recently the following was shown:

**Lemma 1.3 ([7]).** Let the Lipschitz domain $\Omega$ be star-shaped with respect to the origin. Then there exists a constant $C > 0$ independent of $k \geq k_0$ such that for the operators $A_k, A'_k$ there holds

\[ \|A_k^{-1}\|_{L^2(\Gamma) \to L^2(\Gamma)} = \|(A'_k)^{-1}\|_{L^2(\Gamma) \to L^2(\Gamma)} \leq C. \]

We will see that in the context of high order Galerkin BEM (see Corollaries 3.18, 3.21), a case of particular interest is the one where $\|A_k^{-1}\|_{L^2(\Gamma) \to L^2(\Gamma)}$ grows only polynomially in $k$. Lemma 1.3 indicates that this assumption is reasonable. The numerical examples in Section 4 include geometries that are not star-shaped, but where this polynomial growth assumption is satisfied.

1.2. Galerkin Discretization. Associated with the operators $A_k$ and $A'_k$ are the sesquilinear forms $a_k$ and $a'_k$ (which are linear in the first and anti-linear in the second argument) given by

\begin{align*}
a_k(u, v) &:= (A_k u, v)_0 = \frac{1}{2}(u, v)_0 + (K_k u, v)_0, \\
a'_k(u, v) &:= (A'_k u, v)_0 = \frac{1}{2}(u, v)_0 + (K'_k u, v)_0.
\end{align*}

Here and in the following, we use the short-hand $(\cdot, \cdot)_0$ to denote the $L^2(\Gamma)$-inner product. Given $f \in L^2(\Gamma)$ we study the operator equations $A_k u = f$ and $A'_k u = f$. 
For a given $X_N \subset L^2(\Gamma)$, these operator equations are discretized as follows:

\begin{align}
\text{find } u_N & \in X_N \text{ s.t. } a_k(u_N, v) = (f, v)_0 \quad \forall v \in X_N, \quad (1.7) \\
\text{find } u'_N & \in X_N \text{ s.t. } a'_k(u'_N, v) = (f, v)_0 \quad \forall v \in X_N. \quad (1.8)
\end{align}

Since $A_k$ and $A'_k$ are compact perturbations of the identity operator, unique solvability of (1.7), (1.8) and quasi-optimality is given if $X_N$ is sufficiently large. The purpose of the present paper is to make the $k$-dependence of the required approximation properties of $X_N$ explicit.

2. Regularity. Subsections 2.1 and 2.2 collect results from [16]. These results, however, are simplified to be directly applicable to the $L^2$-convergence theory, which is the focus of the present paper.

2.1. Decomposition of $A_k$ and $A'_k$.

2.1.1. Decomposition of $A_k$. The following lemma is derived from [16, Lemma 5.5, Remark 5.6]:

**Lemma 2.1** (decomposition of $A_k$). Fix $q \in (0, 1)$ and $\alpha \in \mathbb{R}$. Then the operator $A_k$ can be written as

$$A_k = \frac{1}{2} + K_0 + i\alpha V_0 + R_A + k[\tilde{A}_A]$$

where $R_A : L^2(\Gamma) \to H^1(\Gamma)$ and $\tilde{A}_A$ satisfy for some constant $C > 0$, which is independent of $k \geq k_0$ and $q$, and a constant $\gamma > 0$, which is independent of $k \geq k_0$,

$$\|R_A\|_{H^1(\Gamma) \rightarrow L^2(\Gamma)} \leq Ck, \quad \|R_A\|_{L^2(\Gamma) \rightarrow L^2(\Gamma)} \leq q, \quad \tilde{A}_A \in \mathfrak{A}(Ck\|\varphi\|_{L^2(\Gamma)}^2, \gamma, \Omega_R) \quad \forall \varphi \in L^2(\Gamma).$$

**Remark 2.2.** Our reason for permitting the choice $\alpha \neq 0$ in the decomposition of Lemma 2.1 is that the operator $1/2 + K_0$ has a one-dimensional kernel. However, the operator $1/2 + K_0 - iV_0$ is invertible (see, e.g., [16, Lemma 2.5]). We will see below that it is convenient to work with a decomposition of $A_k$ whose leading term is invertible.

The next lemma is derived from [16, Lemma 5.7, Remark 5.8]:

**Lemma 2.3** (decomposition of $A'_k$). Fix $q \in (0, 1)$ and $\alpha \in \mathbb{R}$. Then the operator $A'_k$ can be written in the form

$$A'_k = \frac{1}{2} + K'_0 + i\alpha V_0 + R_{A'} + k[\tilde{A}_{A'}, 1] + [\partial_n \tilde{A}_{A', 2}]$$

where $R_{A'} : L^2(\Gamma) \to H^1(\Gamma)$ and $\tilde{A}_{A'}$ satisfy for some constants $C, \gamma > 0$ that are independent of $k \geq k_0$,

$$\|R_{A'}\|_{H^1(\Gamma) \rightarrow L^2(\Gamma)} \leq Ck, \quad \|R_{A'}\|_{L^2(\Gamma) \rightarrow L^2(\Gamma)} \leq q, \quad \tilde{A}_{A', i} \in \mathfrak{A}(Ck\|\varphi\|_{L^2(\Gamma)}^2, \gamma, \Omega_R), \quad \forall \varphi \in L^2(\Gamma), \quad i \in \{1, 2\}.$$

**Remark 2.4.** As in Remark 2.2, the operator $1/2 + K'_0$ has a one-dimensional kernel. However, the operator $1/2 + K'_0 + iV_0$ is invertible (see, e.g., [16, Lemma 2.5]).
2.2. Decomposition of $A_k^{-1}$ and $(A_k')^{-1}$. The following result is taken from [16, Cor. 6.7] and exploits the fact that $A_k$ is $L^2(\Gamma)$-invertible:

**Lemma 2.5.** Let $T$ be a tubular neighborhood of $\Gamma$, and $C_1, \gamma_0 > 0$. Then there exist constants $C, \gamma > 0$ such that for every $g \in \mathfrak{A}(C_1, \gamma_0, T \setminus \Gamma)$ the solution $\phi \in L^2(\Gamma)$ of $A_k \phi = [g]$ satisfies

$$\phi = [u], \quad u \in \mathfrak{A}(CC_1, \gamma, \Omega), \quad C_\phi := C_\gamma (1 + \kappa^{5/2} \|A_k^{-1}\|_{L^2 \to L^2}).$$

For the proof of the next result, we refer to [16, Cor. 6.9] and make use of the fact that $A_k'$ is $L^2(\Gamma)$-invertible:

**Lemma 2.6.** Let $\Gamma$ be analytic, $T$ be a tubular neighborhood of $\Gamma$, and $C_1, C_2, \gamma_0 > 0$. Then there exist constants $C, \gamma > 0$ independent of $k \geq k_0$ such that for all $g_1 \in \mathfrak{A}(C_1, \gamma_0, T \setminus \Gamma), g_2 \in \mathfrak{A}(C_2, \gamma_0, T \setminus \Gamma)$ the solution $\phi \in L^2(\Gamma)$ of $A_k \phi = k[g_1] + [g_2]$ satisfies

$$\phi = [u], \quad u \in \mathfrak{A}(CC_1, \gamma, \Omega), \quad C_\phi := (C_1 + C_2) \left(1 + k^{5/2} \|A_k^{-1}\|_{L^2 \to L^2}\right).$$

We now present the decomposition result for $A_k^{-1}$ of [16, Thm. 6.11]:

**Theorem 2.7 (decomposition of $A_k^{-1}$).** Let $\Gamma$ be analytic. Let $A_k$ be boundedly invertible on $L^2(\Gamma)$. Then there exist constants $C, \gamma > 0$ independent of $k \geq k_0$ with the following properties: The operator $A_k^{-1}$ can be written as

$$A_k^{-1} = A_{Z} + \gamma_0 \gamma_1 A_{\gamma_1} + \gamma_0 \gamma_1 A_{\gamma_1},$$

where the linear operators $A_Z$ and $\tilde{A}_{\gamma_1}$ satisfy for all $f \in H^s(\Gamma)$

$$\|A_Z\|_{L^2 \to L^2} \leq C, \quad \|\tilde{A}_{\gamma_1}\|_{L^2 \to L^2} \leq C.$$  

Finally, we have an analogous result for the adjoint $(A_k')^{-1}$ (see [16, Thm. 6.12]):

**Theorem 2.8 (decomposition of $(A_k')^{-1}$).** Let $\Gamma$ be analytic. Then there exist constants $C, \gamma > 0$ independent of $k \geq k_0$ with the following properties: The operator $(A_k')^{-1}$ can be written as

$$(A_k')^{-1} = A_{Z} + \gamma_1^{\text{ext}} \tilde{A}_{\gamma_1,\text{ext}} + \gamma_1^{\text{int}} \tilde{A}_{\gamma_1,\text{int}}$$

where the linear operators $A_Z$ and $\tilde{A}_{\gamma_1,\text{int}}$ satisfy

$$\|A_Z\|_{L^2 \to L^2} \leq C, \quad \|\tilde{A}_{\gamma_1,\text{int}}\|_{L^2 \to L^2} \leq C.$$  

3. $L^2$-Stability and Convergence. Our stability and convergence theory rests on viewing the operators $A_k$ and $A_k'$ as perturbation of the zero-th order operators $A_0$ and $A_0'$ given by:

$$A_0 = +1/2 + K_0 - W_0, \quad A_0' = +1/2 + K_0' + W_0$$

We view these operators as operators acting on $L^2(\Gamma)$ and note that the operator $A_0'$ is the $L^2(\Gamma)$-adjoints of the operator $A_0$.  

3.1. Regularity Properties of Auxiliary Adjoint Problems. In view of (1.3) we have
\[ a_k(u, v) = a'_{-k}(v, u) \quad \forall u, v \in L^2(\Gamma), \]
which expresses the fact that the \(L^2(\Gamma)\)-adjoint of \(A_k\) is given by \(A'_{-k}\):

**Lemma 3.1.** For every \(k \in \mathbb{R} \setminus \{0\}\) the operators \(A_k\) and \(A'_{-k}\) are \(L^2(\Gamma)\)-adjoints of each other.

We recall from Lemma 2.1, 2.3 that the operators \(A_k - A_0\) and \(A'_{-k} - A'_0\) can be decomposed into two parts, namely, a part that is arbitrarily small as an operator \(L^2(\Gamma) \rightarrow L^2(\Gamma)\) and an operator that maps into a class of analytic functions. In view of this observation and the fact that the operators \(A^{-1}_k\) and \((A'_{-k})^{-1}\) can, by Theorems 2.7, 2.8, be decomposed into a zero-th order operator (that is uniformly bounded in \(k\)) and an operator that maps into a class of analytic functions, we can formulate the following result:

**Lemma 3.2.** Let \(\Gamma\) be analytic. Let \(q, q' \in (0, 1)\) be given. Then
\[
A^{-1}_k(A_k - A_0) = T_A + [\tilde{A}_{k,A, \text{inv}}],
\]
\[
(A'_{-k})^{-1}(A'_{-k} - A'_0) = T_{A'} + k[\tilde{A}_{k,A', \text{inv}, i}] + [\partial_n \tilde{A}_{k,A', \text{inv}, 2}],
\]
where for some \(C, \gamma > 0\) independent of \(k \geq k_0\) and all \(\varphi \in L^2(\Gamma)\):
\[
\|T_A\|_{L^2 \rightarrow L^2} \leq q, \quad \|T_{A'}\|_{L^2 \rightarrow L^2} \leq q',
\]
\[
\tilde{A}_{k,A, \text{inv}} \varphi \in \mathfrak{A}(CC_\varphi, \gamma, \Omega_R), \quad C_\varphi = k^3(1 + k^{5/2}\|A^{-1}_k\|_{L^2 \rightarrow L^2})\|\varphi\|_{L^2(\Gamma)},
\]
\[
\tilde{A}_{k,A', \text{inv}, i} \varphi \in \mathfrak{A}(CC_\varphi, \gamma, \Omega_R), \quad C_{\varphi, i} = (1 + k^{5/2}\|(A'_{-k})^{-1}\|_{L^2 \rightarrow L^2})\|\varphi\|_{L^2(\Gamma)}, \quad i \in \{1, 2\}.
\]

**Proof.** We first prove the decomposition result for \((A'_{-k})^{-1}(A'_{-k} - A'_0)\). From Lemma 2.3 and Theorem 2.8 we get
\[
(A'_{-k})^{-1} = A'_{Z} + [\partial_n \tilde{A}_{A', \text{inv}}],
\]
\[
A'_{-k} - A'_0 = R_{A'} + k[\tilde{A}_{A', 1}] + [\partial_n \tilde{A}_{A', 2}].
\]
Hence, we obtain
\[
(A'_{-k})^{-1} = A'_{Z} R_{A'} + [\partial_n \tilde{A}_{A', \text{inv}}] R_{A'} + (A'_{-k})^{-1} \left( k[\tilde{A}_{A', 1}] + [\partial_n \tilde{A}_{A', 2}] \right).
\]
We set \(T_A := A'_{Z} R_{A'}\). From Theorem 2.8 we know that \(\|A'_{Z}\|_{L^2 \rightarrow L^2}\) is bounded uniformly in \(k\). Lemma 2.3 tells us that \(\|R_{A'}\|_{L^2 \rightarrow L^2}\) can be made arbitrarily small. Hence, \(T_A\) has the desired property. For \(\varphi \in L^2(\Gamma)\) we get from Theorem 2.8 and Lemma 2.3
\[
\tilde{A}_{A', \text{inv}} R_{A'} \varphi \in \mathfrak{A}(CC_\varphi, \gamma, \Omega_R), \quad C_{\varphi, 1} = \left( 1 + k^{5/2}\|(A'_{-k})^{-1}\|_{L^2 \rightarrow L^2} \right)\|\varphi\|_{L^2(\Gamma)},
\]
\[
k \tilde{A}_{A', 1} \varphi, \quad \tilde{A}_{A', 2} \varphi \in \mathfrak{A}(CC_\varphi, \gamma, \Omega_R), \quad C_{\varphi, 2} = \left( 1 + k^{5/2}\|(A'_{-k})^{-1}\|_{L^2 \rightarrow L^2} \right)\|\varphi\|_{L^2(\Gamma)}.
\]
Lemma 2.6 then allows us to define the operators \(\tilde{A}_{k,A', \text{inv}, i}, i \in \{1, 2\}\) with the stated properties.

7
Therefore, \( A_k^{-1}(A_k - A_0) = A_Z R_A + [\tilde{A}_A^{-1}] R_A + A_k^{-1} k[\tilde{A}_A] \). Again, we set \( T_A := A_Z R_A \) and see that its norm can be made arbitrarily small. The properties of \( \tilde{A}_A^{-1} \) given in Theorem 2.7 and those of \( \tilde{A}_A \) given in Lemma 2.1 together with Lemma 2.5 then imply the result.

3.2. Abstract Convergence Analysis. For the approximation space \( X_N \subset L^2(\Gamma) \) we denote by \( \Pi_N^{L^2} : L^2(\Gamma) \to X_N \) the \( L^2(\Gamma) \)-projection onto \( X_N \). It will be useful to quantify the approximation of analytic functions from the space \( X_N \):

**Definition 3.3.** Let \( T \) be a fixed tubular neighborhood of \( \Gamma \). For every \( \gamma > 0 \), define \( \eta_1(N, k) \), \( \eta_2(N, k, \gamma) \), \( \eta(N, k, \gamma) \) by

\[
\eta_1(N, k, \gamma) := \sup \{ \| k[u] - \Pi_N^{L^2} k[u] \|_{L^2(\Gamma)} : u \in \mathfrak{A}(1, \gamma, T \setminus \Gamma) \},
\]

\[
\eta_2(N, k, \gamma) := \sup \{ \| \partial_n u - \Pi_N^{L^2} \partial_n u \|_{L^2(\Gamma)} : u \in \mathfrak{A}(1, \gamma, T \setminus \Gamma) \},
\]

\[
\eta(N, k, \gamma) := \eta_1(N, k, \gamma) + \eta_2(N, k, \gamma).
\]

We point out that, by linearity, we have for functions \( u \in \mathfrak{A}(C_u, \gamma, T \setminus \Gamma) \) the bound \( \| k[u] - \Pi_N^{L^2} k[u] \|_{L^2(\Gamma)} \leq C_u \eta_1(N, k, \gamma) \) and an analogous estimate for \( \| \partial_n u - \Pi_N^{L^2} \partial_n u \|_{L^2(\Gamma)} \).

We will also need stability properties of the spaces \( X_N \) for the operators \( A_0 \) and \( A_0' \), for future reference we formulate these as assumptions:

**Assumption 3.4.** The space \( X_N \) satisfies a uniform discrete inf-sup condition for the operator \( 1/2 + K_0 - W_0 \), i.e., there exists \( \gamma_0 > 0 \) independent of \( N \) such that

\[
0 < \gamma_0 \leq \inf_{0 \neq u \in X_N} \sup_{0 \neq v \in X_N} \frac{|(1/2 + K_0 - iW_0)u, v|_0}{\| u \|_0 \| v \|_0}.
\]

The inf-sup condition (3.3) is equivalent to

\[
0 < \gamma_0 \leq \inf_{0 \neq u \in X_N} \sup_{0 \neq v \in X_N} \frac{|(1/2 + K_0' + iW_0)u, v|_0}{\| u \|_0 \| v \|_0},
\]

with the same constant \( \gamma_0 > 0 \).

**Remark 3.5.** For the present case of smooth surfaces \( \Gamma \), the operators \( K_0 : L^2(\Gamma) \to L^2(\Gamma) \) and \( V_0 : L^2(\Gamma) \to L^2(\Gamma) \) are compact. Hence, Assumption 3.4 is satisfied, for example, for standard \( hp \)-BEM spaces, when the discretization is sufficiently fine.

We close this subsection with two approximation results.

**Lemma 3.6.** Let \( \Gamma \) be analytic. Let \( q \in (0, 1) \) be given and let \( \eta(N, -k, \gamma) \) be given by Definition 3.3. Then

\[
\| (\text{Id} - \Pi_N^{L^2})(A_{-k} - A_0') \|_{L^2 \to L^2} \leq q + C k \eta(N, -k, \gamma),
\]

\[
\| (\text{Id} - \Pi_N^{L^2})(A_{-k}^{-1} - A_0') \|_{L^2 \to L^2} \leq q + C \left\{ 1 + k^{5/2} \| (A_{-k}^{-1}) \|_{L^2 \to L^2} \right\} \eta(N, -k, \gamma),
\]

for a \( \gamma > 0 \) that is independent of \( k \geq k_0 \) (but possibly depends on \( q \)).
**Definition 3.3.** Then by the triangle inequality \( \|A\| \) can be made arbitrarily small. Thus, \( \|\text{Id} - \Pi_N^{-2}\|_{L^2} \leq \|\Pi_N^{-2}\|_{L^2} \) can be made arbitrarily small. The \( L^2(\Gamma) \)-approximation of the remaining terms \( [\tilde{A}_{\Gamma'}^{-1}]; [\partial_n \tilde{A}_{\Gamma'}^{-1}] \) directly lead to the stated estimate.

From Lemma 3.2 we get the decomposition \( (A_{k'}^{-1}(A_k-A_0)) = T_k + k[\tilde{A}_{k'}^{-1}; \Pi_N^{-2}] \), where \( \|T_k\|_{L^2} \) can be made arbitrarily small. It is easy to see that the \( L^2(\Gamma) \)-approximation of the remaining terms leads to the stated estimate. □

**Lemma 3.7.** Let \( \Gamma \) be analytic. Let \( q \in (0, 1) \) be given and let \( \eta_1(N, k, \gamma) \) be given by Definition 3.3. Then

\[
\|\text{Id} - \Pi_N^{-2}\|_{L^2, \infty} \leq q + Ck\eta_1(N, k, \gamma),
\]

\[
\|\text{Id} - \Pi_N^{-2}\|_{L^2, \infty}^{-1} \leq q + Ck^2 \left(1 + k^{5/2}\|A_k^{-1}\|_{L^2}^{-1} \right) \eta_1(N, k, \gamma),
\]

for a \( \gamma > 0 \) that is independent of \( k \geq k_0 \) (but possibly depends on \( q \)).

**Proof.** The proof follows the lines of Lemma 3.6. The estimate for \( \|\text{Id} - \Pi_N^{-2}\|_{L^2, \infty} \) follows from Lemma 2.1. Lemma 3.2 finally leads to the second bound. □

### 3.2.1. The Case of the Operator \( A_k \)

At the heart of our analysis is the following quasi-optimality result:

**Theorem 3.8.** Let \( \Gamma \) be analytic, \( \eta_1, \eta_2 \) be given by Definition 3.3, and let Assumption 3.4. Then there exist constants \( \varepsilon, \gamma > 0 \) independent of \( k \geq k_0 \) such that the assumption

\[
k\eta_1(N, k, \gamma) \leq \varepsilon, \quad \left(1 + k^{5/2}\|A_k^{-1}\|_{L^2}^{-1} \right) \eta_1(N, k, \gamma) \leq \varepsilon
\]

the following is true: If \( u \in L^2(\Gamma) \) and \( u_N \in X_N \) are two functions that satisfy the Galerkin orthogonality

\[
a_k(u - u_N, v) = 0 \quad \forall v \in X_N \]

then with \( \gamma_0 \) as stated in Assumption 3.4

\[
\|u - u_N\|_{L^2(\Gamma)} \leq 2 \left(1 + \frac{\|A_k\|_{L^2}^{-1}}{\gamma_0} \right) \inf_{u_N \in X_N} \|u - w_N\|_{L^2(\Gamma)}.
\]

**Proof.** We introduce the abbreviation \( e := u - u_N \). Let \( w_N \in X_N \) be arbitrary. Then by the triangle inequality

\[
\|e\| \leq \|u - w_N\| + \|u_N - w_N\|.
\]

Hence, we have to estimate \( \|u_N - w_N\| \). By the discrete inf-sup condition we can find a \( N \in X_N \) with \( \|v_N\| = 1 \) and \( \gamma_0\|u_N - w_N\| \leq (A_0(u_N - w_N), v_N) \). With the Galerkin orthogonality \( (A_k(u - u_N), v_N) = 0 \), we then obtain

\[
\gamma_0 \|u_N - w_N\| \leq ((A_0 - A_k)(u_N - w_N), v_N) + (A_k(u_N - w_N), v_N) \]

\[
= ((A_0 - A_k)(u_N - w_N), v_N) + (A_k(u - w_N), v_N) \]

\[
= (A_k - A_0)e, v_N) + (A_0(u - w_N), v_N) = \|A_0\|_{L^2} \|u - w_N\| + (A_k - A_0)e, v_N) \]

\[
\leq \|A_0\|_{L^2} \|u - w_N\| + (A_k - A_0)e, v_N) \leq \|A_0\|_{L^2} \|u - w_N\| + (A_k - A_0)e, v_N) \]

\[
(3.9)
\]
In order to treat the term \(((A_k - A_0)e, v_N)_0\) we define \(\psi \in L^2(\Gamma)\) by
\[
((A_k - A_0)e, v_N)_0 = (z, A'_{-k} \psi)_0 \quad \forall z \in L^2(\Gamma).
\] (3.10)

Lemma 3.2 tells us
\[
\psi = (A'_{-k})^{-1}(A'_{-k} - A'_0)v_N
\] (3.11)

By selecting \(z = e\) in (3.10), using Galerkin orthogonality satisfied by the error \(e\) and orthogonality properties of \(\Pi^2_N\) we obtain
\[
\begin{align*}
((A_k - A_0)e, v_N)_0 & = (e, A'_{-k} \psi)_0 = (A_k e, \psi) - \Pi^2_N(\psi) \\
& = (A_0 e, \psi - \Pi^2_N(\psi)) + ((A_k - A_0)e, \psi - \Pi^2_N(\psi)) \\
& = (A_0 e, \psi - \Pi^2_N(\psi)) + ((A_k - A_0)e, \psi - \Pi^2_N(\psi) - (A'_{-k} - A'_0)\psi).
\end{align*}
\]

Hence, from (3.11) and \(\|v_N\|_0 = 1\)
\[
\begin{align*}
|((A_k - A_0)e, v_N)_0| & \leq \left\{ \|A_0\|_{L^2} \|A_k - A_0\|_{L^2} + \|\text{Id} - \Pi^2_N\|_{L^2} \right\} \\
& \times \|\text{Id} - \Pi^2_N\|_{(A'_{-k})^{-1}(A'_{-k} - A'_0)}_{L^2} \|e\|_0.
\end{align*}
\]

From Lemmata 3.6, 3.7 we get for arbitrary \(q \in (0,1)\)
\[
|((A_k - A_0)e, v_N)_0| \leq \left\{ \|A_0\|_{L^2} + q + Ck\eta_1(N, k, \gamma) \right\} \\
\times \left\{ q + C \left( 1 + k^{5/2}(A'_{-k})^{-1}\|L^2\|_{L^2} \right) \eta(N, k, \gamma) \right\} \|e\|_0.
\] (3.12)

Select now \(q \in (0,1)\) such that \((\|A_0\|_{L^2} + q)q < 1/2\). Then the constants \(C\) and \(\gamma\) in (3.12) are fixed and independent of \(k \geq k_0\). We can furthermore select \(\varepsilon > 0\) independent of \(k\) such that the assumption (3.5) then guarantees that the product of the two curly braces in (3.12) is bounded by 1/2. Combining (3.8), (3.9), and (3.12) therefore yields
\[
\|e\|_0 \leq \left( 1 + \frac{\|A_0\|_{L^2}}{\gamma_0} \right) \|u - w_N\|_0 + \frac{1}{2} \|e\|_0,
\]

which leads to the desired estimate. \(\square\)

Theorem 3.8 provides quasi-optimality under the assumption that \(u_N \in X_N\) exists. However, the discrete inf-sup condition follows easily from Theorem 3.8. In particular, we obtain that the discrete inf-sup constant is, up to a constant which is independent of \(k\), and \(N\), the inf-sup constant for the continuous problem. This is a consequence of the following, general result:

**THEOREM 3.9.** Let \(X\) be a Hilbert space with norm \(\| \cdot \|_X\). Let \(X_N \subset X\) be a finite-dimensional subspace. Let \(a : X \times X \to \mathbb{C}\) be a continuous sesquilinear form that satisfies the inf-sup condition
\[
0 < \gamma_a \leq \inf_{0 \neq u \in X} \sup_{0 \neq v \in X} \frac{|a(u, v)|}{\|u\|_X \|v\|_X}.
\]

Let \(C_{\text{opt}} > 0\) be such that any pair \((u, u_N) \in X \times X_N\) that satisfies the Galerkin orthogonality
\[
a(u - u_N, v) = 0 \quad \forall v \in X_N
\]
enjoys the best approximation property
\[\|u - u_N\|_X \leq C_{qopt} \inf_{v \in X_N} \|u - v\|_X.\]
Then the discrete inf-sup condition holds, i.e.,
\[\inf_{0 \neq u \in X_N} \sup_{0 \neq v \in X_N} \frac{|a(u, v)|}{\|u\|_X \|v\|_X} =: \gamma_N \geq \gamma_0 \frac{1}{1 + C_{qopt}} > 0.\]

Proof. We first show that the restriction of the sesquilinear form \(a\) to \(X_N \times X_N\) induces an injective operator \(X_N \to X_N'\). To see this, let \(u_N \in X_N\) satisfy \(a(u_N, v) = 0\) for all \(v \in X_N\). Our assumption is then applicable to the pair \((u, u_N)\) and we get \(\|u_N\|_X = \|u - u_N\|_X \leq C_{qopt} \inf_{v \in X_N} \|u - v\|_X \leq C_{qopt}\|u\|_X = 0\). By dimension arguments, therefore, the Galerkin projection operator \(P_N : X \to X_N\) given by
\[a(u - P_N u, v) = 0 \quad \forall v \in X_N\]
is well-defined. Additionally, the quasi-optimality assumption produces the stability result \(|P_N u|_X \leq \|u\|_X + \|u - P_N u\|_X \leq (1 + C_{qopt})\|u\|_X\).
It is known that
\[\inf_{0 \neq u \in X_N} \sup_{0 \neq v \in X_N} \frac{|a(u, v)|}{\|u\|_X \|v\|_X} = \inf_{0 \neq u \in X_N} \sup_{0 \neq v \in X_N} \frac{|a(u, v)|}{\|u\|_X \|v\|_X} = \inf_{0 \neq u \in X_N} \sup_{0 \neq v \in X_N} \frac{|a(u, v)|}{\|u\|_X \|v\|_X}.\]
We will therefore just compute the second inf-sup constant. To that end, let \(v \in X_N \setminus \{0\}\). Then by Galerkin orthogonality and \(v \in X_N\)
\[\sup_{0 \neq u \in X_N} \frac{|a(u, v)|}{\|u\|_X \|v\|_X} = \sup_{0 \neq u \in X} \frac{|a(P_N u, v)|}{\|P_N u\|_X \|v\|_X} = \sup_{0 \neq u \in X} \frac{|a(u, v)|}{\|P_N u\|_X \|v\|_X} \geq \frac{1}{1 + C_{qopt}} \sup_{0 \neq u \in X} \frac{|a(u, v)|}{\|u\|_X \|v\|_X} \geq \frac{1}{1 + C_{qopt}} \gamma_N.\]
Taking the infimum over all \(v \in X_N\) concludes the argument. [Q.E.D.]
Combining Theorems 3.9 and 3.8 yields:
COROLLARY 3.10. Assume the hypotheses of Theorem 3.8. If the approximation space \(X_N\) satisfies (3.5), then (1.7) is uniquely solvable and the quasi-optimality result (3.7) is true.

3.2.2. The Case of the Operator \(A_k\). The results of Section 3.2.1 for the discretization of the operator \(A_k\) have clearly analogs for the discretization of the operator \(A_k\). Since the procedure is very similar to that of Section 3.2.1, we merely state the results and leave their proofs to the reader.
THEOREM 3.11. Let \(\Gamma\) be analytic, \(\eta_1, \eta\) be given by Definition 3.3, and let Assumption 3.4 be valid. Then there exist constants \(\varepsilon, \gamma > 0\) independent of \(k \geq k_0\) such that under the assumption
\[k \eta(N, k, \gamma) \leq \varepsilon, \quad k^2 \left(1 + k^{5/2} \|A_k^{-1}\|_{L^2 \to L^2}\right) \eta_1(N, -k, \gamma) \leq \varepsilon\]
the following is true: If \(u \in L^2(\Gamma)\) and \(u_N \in X_N\) are two functions that satisfy the Galerkin orthogonality
\[a_k(u - u_N, v) = 0 \quad \forall v \in X_N\]
then with \( \gamma_0 \) as stated in Assumption 3.4

\[
\|u - u_N\|_{L^2(\Gamma)} \leq 2 \left( 1 + \frac{\|A_0\|_{L^2 - L^2}}{\gamma_0} \right) \inf_{w_N \in X_N} \|u - w_N\|_{L^2(\Gamma)}. \tag{3.15}
\]

Proof. See Appendix A. \( \square \)

**Corollary 3.12.** Assume the hypotheses of Theorem 3.11. If the approximation space \( X_N \) satisfies (3.13), then (1.8) is uniquely solvable and the quasi-optimality result (3.15) is true.

### 3.3. Classical hp-BEM

The analysis of the preceding section shows that the stability and convergence analysis of discretizations of the operators \( A_k \) and \( A_k' \) can be reduced to questions of approximability. As an example of the abstract theory, we consider the classical hp-BEM. We restrict our attention here to a situation in which the \( h \)-dependence can be obtained by scaling arguments.

We let \( \tilde{K}^{d-1} = \{x \in \mathbb{R}^{d-1} | 0 < x_i < 1, \sum_{i=1}^{d-1} x_i < 1\} \) and \( \hat{K}^{d} = \{x \in \mathbb{R}^{d} | 0 < x_i < 1, \sum_{i=1}^{d} x_i < 1\} \) be the references simplices in \( \mathbb{R}^{d-1} \) and \( \mathbb{R}^{d} \). By \( T \) we denote a triangulation of \( \Gamma \) into elements \( K \in T \), where the elements \( K \) are assumed to be the images of \( \tilde{K}^{d-1} \) under smooth element maps \( F_K : \tilde{K}^{d-1} \to K \). The element maps \( F_K \) are furthermore required to be \( C^1 \)-diffeomorphisms between \( \tilde{K}^{d-1} \) and \( K \).

For \( p \in \mathbb{N}_0 \), we then define the \( hp \)-BEM space \( S^p(T) \) by

\[
S^p(T) = \{u \in L^2(\Gamma) | u|_K \circ F_K \in \mathcal{P}_p \quad \forall K \in T\}, \tag{3.16}
\]

where \( \mathcal{P}_p \) is the vector space of all polynomials of degree \( p \).

To motivate the class of triangulations of Assumption 3.15 below, we consider the following two examples:

**Example 3.13.** Let \( d = 2 \) and \( \Gamma = \partial \Omega \subset \mathbb{R}^{d} \) be an analytic curve. Let the analytic function \( R : [0, 1] \to \Gamma \) be a parametrization of \( \Gamma \). Denote by \( \tilde{T} \) a uniform mesh on \([0, 1]\) with mesh size \( h \). Define the mesh \( T \) by “transporting” the elements of \( \tilde{T} \) to \( \Gamma \) via \( R \). Then the element maps \( F_K \) have the form \( F_K = R \circ A_K \), where \( A_K \) is an affine map with \( \|\nabla A_K\| \leq C h \) and \( \|\nabla^{-1} A_K\| \leq C h^{-1} \). These element maps have the form stipulated in Definition 3.15 below.

**Example 3.14.** Let \( d = 3 \) and \( \Gamma = \partial \Omega \) be analytic. Let \( T^d \) be a patchwise constructed mesh on the domain \( \Omega \) as given in [18, Example 5.1]. There, the element maps \( F_K : \hat{K}^{d} \to K \) have the form \( F_K = R_K \circ A_K \) for an affine map \( A_K \) with \( \|\nabla A_K\| \leq C h \) and \( \|\nabla^{-1} A_K\| \leq C h^{-1} \) and the functions \( R_K \) satisfy

\[
\|\nabla R_K^{-1}\|_{L^\infty(\hat{K}^d)} \leq C_{\text{metric}}, \quad \|\nabla^n R_K\|_{L^\infty(\hat{K}^d)} \leq C_{\text{metric}} \gamma^n n! \quad \forall n \in \mathbb{N}_0;
\]

here, \( \hat{K}^{d} = A_K(\hat{K}^{d}) \) is the image of the reference simplex \( \hat{K}^{d} \) under the affine map \( A_K \). The mesh \( T^d \) on the domain \( \Omega \) induces in a canonical way a mesh on \( \Gamma = \partial \Omega \). This trace mesh has the properties specified in the Definition 3.15 below.

The two examples motivate the following assumptions on the triangulation of \( \Gamma \):

**Definition 3.15 (quasi-uniform triangulation).** A triangulation \( \mathcal{T}_h \) of the analytic manifold \( \Gamma \) is said to be a quasi-uniform mesh with mesh size \( h \) if the following is true: Each element map \( F_K \) can be written as \( F_K = R_K \circ A_K \), where \( A_K \) is an affine map and the maps \( R_K \) and \( A_K \) satisfy for constants \( C_{\text{affine}}, C_{\text{metric}}, \gamma_\mathcal{T} > 0 \) independent of \( h \):

\[
\|\nabla A_K\|_{L^\infty(\hat{K}^d)} \leq C_{\text{affine}} h, \quad \|\nabla^{-1} A_K\|_{L^\infty(\hat{K}^d)} \leq C_{\text{affine}} h^{-1}
\]

\[
\|\nabla R_K^{-1}\|_{L^\infty(\hat{K}^d)} \leq C_{\text{metric}}, \quad \|\nabla^n R_K\|_{L^\infty(\hat{K}^d)} \leq C_{\text{metric}} \gamma_\mathcal{T}^n n! \quad \forall n \in \mathbb{N}_0.
\]

12
Here, \( \hat{K} = A_K(\hat{K}) \).

**Lemma 3.16.** Let \( \Gamma \) be analytic. Let \( T_h \) be a quasi-uniform triangulation of \( \Gamma \) with mesh size \( h \) in the sense of Definition 3.15. Fix a tubular neighborhood \( T \) of \( \Gamma \). Let \( X_N = S^p(T_h) \). Let \( C > 0 \) be fixed and assume that \( h, p, \text{ and } k \) satisfy

\[
\frac{kh}{p} \leq \tilde{C}.
\]

Then, for every \( \gamma > 0 \) there exist \( C, \sigma > 0 \) (independent of \( h, p, \text{ and } k \geq k_0 \)) such that

\[
\eta(N,k,\gamma) \leq \eta_1(N,k,\gamma) + \eta_2(N,k,\gamma) \leq C k^{3/2} \left\{ \left( \frac{h}{\sigma + h} \right)^{p+1} + \left( \frac{kh}{p} \right)^{p+1} \right\}.
\]

**Proof.** We only sketch the arguments for the bound on \( \eta_1 \), which quantifies how well the jump \( \mathcal{K}[u] \) of a piecewise analytic function can be approximated from \( X_N = S^p(T_h) \). Using [16, Lemma B.5], we may assume that \( u|_{\Omega^+} = 0 \). Denote by \( \tilde{n}(x) \) the outer normal vector of \( \Omega \) at the point \( x \in \Gamma \).

**1. step:** Let \( T_h \) be a tubular neighborhood of \( \Gamma \) of width \( O(h) \) and \( u \in \mathcal{A}(C_u, \gamma_u, T \setminus \Gamma) \) for a fixed tubular neighborhood of \( \Gamma \). We assume that \( h \) is small (as compared to the width of \( T \)). With the aid of [13, Lemma 2.1] and the interpolation inequality

\[
\|v\|_{L^2(\Omega)} \lesssim \|v\|_{H^2(\Omega)}^{1/2} \|v\|_{H^1(\Omega)}^{1/2},
\]

we conclude

\[
\|\nabla^n u\|_{L^2(\Omega)} \leq C \sqrt{kh} C_u(\gamma_u)^n \max\{k, n+1\}^n \quad \forall n \in \mathbb{N}_0,
\]

where the constants \( C, \gamma_u \) are independent of \( k \geq k_0 \) and \( h \).

**2. step:** The reference simplex \( \hat{K}^d \) can be written in the form \( \hat{K}^d = \{(\hat{x}, z) \mid 0 < z < 1, \hat{x} \in z\hat{K}^{d-1}\} \). The element maps \( F_K : \hat{K}^{d-1} \to \Gamma \) have the form \( F_K = R_K \circ A_K \).

Define

\[
A^d_K : \hat{K}^d \ni (\hat{x}, z) \mapsto (A_K(\hat{x}), hz), \\
R^d_K : \hat{K}^d \ni (\hat{x}, z) \mapsto R_K(\hat{x}) - z\tilde{n}(R_K(\hat{x}));
\]

here \( \hat{K}^d \) is the image of \( \hat{K}^d \) under \( A^d_K \), and \( \hat{x} \in \hat{K}, z \in \mathbb{R} \). The assumption on \( A_K \) implies readily that \( A^d_K : \hat{K}^d \to \hat{K}^d \) satisfies

\[
\|\nabla A^d_K\|_{L^\infty(\hat{K}^d)} \leq C h, \\
\|\nabla A^d_K\|_{L^\infty(\hat{K}^d)}^{-1} \leq C h^{-1};
\]

for a constant \( C \) that is independent of \( h \). The analyticity of \( \Gamma \) implies furthermore that the function \( R^d_K \) satisfies for some constants \( c_0, C_g, \gamma_g \) that depend solely on \( \Gamma \) and the constants \( C_{\text{metric}}, \gamma_T \)

\[
\|\nabla R^d_K\|_{L^\infty(\hat{K}^d)}^{-1} \geq c_0, \\
\|\nabla^n R^d_K\|_{L^\infty(\hat{K}^d)} \leq C g \gamma g^n ! \quad \forall n \in \mathbb{N}_0.
\]

**3. step:** The images \( K^d = (R^d_K \circ A^d_K)(\hat{K}^d) \) lie in a tubular neighborhood \( T_h \) of \( \Gamma \) that has width \( O(h) \). Furthermore, geometric considerations imply a finite overlap property, namely, the existence of a constant \( M > 0 \) such that any \( x \in \Omega \) is in no more than \( M \) of these sets:

\[
\sup_{x \in \Omega} |\{ K \in T_h \mid x \in K^d \}| \leq M.
\]

(3.18)
4. step: Define for each $K \in T_h$ the constant
\[
C_K^2 := \sum_{n \in \mathbb{N}_0} \frac{1}{(2\gamma_u^{\max} \max\{k, n\})^2} \|\nabla^n u\|_{L^2(K)}^2.
\] (3.19)
and note that (3.17) and (3.18) imply
\[
\sum_{K \in T_h} C_K^2 \leq M \sum_{n \in \mathbb{N}_0} \left( \frac{1}{2\gamma_u^{\max} \max\{k, n+1\}} \right)^2 \|\nabla^n u\|_{L^2(T_h)}^2 \leq \frac{4}{3} CMC_u^2 k h.
\] (3.20)

5. step: We have $u|_{\Omega^d} \in \mathcal{A}(C_K, 2\gamma_u^{\max}, K^d)$, and [18, Lemma C.1] implies that the function $u \circ R_K^d$ satisfies $u \circ R_K^d \in \mathcal{A}(CC_K, \gamma_u^{\max}, K^d)$, where the constants $C$ and $\gamma_u$ depend solely on $\gamma_u^{\max}$, $\gamma_y$, and $C_y$. Since the map $A_K^d$ is affine and $F_K^d = R_K^d \circ A_K^d$, we get for constants $\gamma, \gamma$ independent of $k$ and $h$
\[
\|\nabla^n (u \circ F_K^d)\|_{L^2(\Omega^d)} \leq CC_K^{-d/2}(\gamma h)^n \max\{k, n\} \quad \forall n \in \mathbb{N}_0.
\]
Next, [18, Lemma C.2] gives for constants $C, \sigma > 0$ independent of $h, p, n \geq k_0$
\[
\inf_{n \in \mathcal{P}_p} \|u \circ F_K^d - \pi\|_{L^\infty(\Omega^d)} \leq CC_K^{-d/2} \left( \left( \frac{h}{\sigma + h} \right)^{p+1} + \left( \frac{kh}{\sigma p} \right)^{p+1} \right),
\]
where $\mathcal{P}_p$ is the space of $d$-variate polynomials of degree $p$. Hence, taking the trace on the $d-1$-dimensional face $\partial \Omega^d$ produces
\[
\inf_{n \in \mathcal{P}_p} \|u \circ F_K - \pi\|_{L^\infty(\Omega)} \leq CC_K^{-d/2} \left( \left( \frac{h}{\sigma + h} \right)^{p+1} + \left( \frac{kh}{\sigma p} \right)^{p+1} \right),
\]
where $\mathcal{P}_p$ denotes the space of $d-1$-variate polynomials of degree $p$. Scaling back to the element $K$ and summing over all elements $K \in T_h$ yields
\[
\inf_{n \in \mathcal{P}(T_h)} \|u - \pi\|_{L^2(\Omega)} \leq \sum_{K \in T_h} CC_K^2 k h^{-d-1} \left( \left( \frac{h}{\sigma + h} \right)^{p+1} + \left( \frac{kh}{\sigma p} \right)^{p+1} \right)^2
\]
\[
\leq CC_K^2 k \left( \left( \frac{h}{\sigma + h} \right)^{p+1} + \left( \frac{kh}{\sigma p} \right)^{p+1} \right)^2.
\]
Recalling that that we are actually interested in the approximation of the function $ku$ instead of $u$, we see that we have obtained the desired bound for $\eta_1$.

**Theorem 3.17 (quasi-optimality for $A$).** Let $\Gamma$ be analytic. Let $T_h$ a quasi-uniform mesh on $\Gamma$ of mesh size $h$ in the sense of Definition 3.15. Let $X_N = S^p(T_h)$. Then there exist constants $C, \varepsilon, \sigma > 0$ independent of $h, k, p$ such that the following is true: If the scale resolution condition
\[
\left\{ k^{5/2} + k^4 \|(A_{-K})^{-1}\|_{L^2(\Omega)} \right\} \left\{ \left( \frac{h}{\sigma + h} \right)^{p+1} + \left( \frac{kh}{\sigma p} \right)^{p+1} \right\} \leq \varepsilon
\] (3.21)
is satisfied, then (1.7) has a unique solution $u_N$ which satisfies
\[
\|u - u_N\|_{L^2(\Omega)} \leq C \inf_{v \in \mathcal{P}(T_h)} \|u - v\|_{L^2(\Gamma)},
\] (3.22)
where $C > 0$ is independent of $k \geq k_0$.

**Proof.** Combine Theorem 3.8 with Lemma 3.16.

We now turn to a corollary covering the case of polynomial growth of $k \mapsto \| (A_{k}^{'})^{-1} \|_{L^2 \to L^2}$. This assumption is quite reasonable in view of Lemma 1.3 (which stated that $\beta = 0$ in the following corollary for the special case of star-shaped geometries).

**Corollary 3.18.** Assume the hypotheses of Theorem 3.17. Assume additionally the existence of $C, \beta \geq 0$ independent of $k$ such that

\[
\| (A_{k}^{'})^{-1} \|_{L^2 \to L^2} \leq C k^\beta. \tag{3.23}
\]

Then there exist constants $C_1, C_2$ independent of $h, k,$ and $p$ such that for

\[
\frac{hk}{p} \leq C_1 \quad \text{and} \quad p \geq C_2 \log k \tag{3.24}
\]

the quasi-optimality assertion (3.22) of Theorem 3.17 is true.

**Remark 3.19.** Corollary 3.18 can be phrased in a different way: the onset of quasi-optimality of the BEM is guaranteed for the choice

\[
p = \left\lceil C_2 \log k \right\rceil \quad \text{and} \quad h = C_1 \frac{p}{k}.
\]

The corresponding problem size $N := \dim S^p(T_h)$ is given by $N = \dim S^p(T_h) \sim h^{-(d-1)} p^{d-1} \sim k^{d-1}$; i.e., the onset of quasi-optimality of the BEM is achieved with a fixed number of degrees of freedom per wavelength.

Results corresponding to the above ones for the operator $A_k$ hold for the operator $A_k^{'}.$ We merely record the statements.

**Theorem 3.20 (quasi-optimality for $A'$).** Let $\Gamma$ be analytic. Let $T_h$ a quasi-uniform mesh of mesh size $h$ in the sense of Definition 3.15. Let $X_N = S^p(T_h).$ Then there exist constants $C, \varepsilon, \sigma > 0$ independent of $h, k,$ and $p$ such that the following is true: If the scale resolution condition

\[
\left\{ k^{7/2} + k^6 \| A_k^{-1} \|_{L^2 \to L^2} \right\} \left\{ \left( \frac{h}{\sigma + h} \right)^{p+1} + \left( \frac{kh}{\sigma p} \right)^{p+1} \right\} \leq \varepsilon \tag{3.25}
\]

is satisfied, then (1.8) has a unique solution $u_N$ which satisfies

\[
\| u - u_N \|_{L^2(\Gamma)} \leq C \inf_{v \in S^p(T_h)} \| u - v \|_{L^2(\Gamma)}, \tag{3.26}
\]

where $C > 0$ is independent of $k$.

**Corollary 3.21.** Assume the hypotheses of Theorem 3.20. Assume additionally the existence of $C, \beta \geq 0$ independent of $k$ such that $\| A_k^{-1} \|_{L^2 \to L^2} \leq C k^\beta.$ Then there exist constants $C_1, C_2$ independent of $h, k,$ and $p$ such that for $\frac{hk}{p} \leq C_1$ and $p \geq C_2 \log k$ the quasi-optimality assertion (3.26) of Theorem 3.20 is true.

**Remark 3.22.** As in Remark 3.22, Corollary 3.21 can be phrased in a different way: the onset of quasi-optimality of the BEM is guaranteed for the choice $p = \left\lceil C_2 \log k \right\rceil$ together with $h = C_1 \frac{p}{k}.$ The corresponding problem size $N := \dim S^p(T_h)$ is given by $N = \dim S^p(T_h) \sim h^{-(d-1)} p^{d-1} \sim k^{d-1}$; i.e., the onset of quasi-optimality of the BEM is achieved with a fixed number of degrees of freedom per wavelength.
4. Numerical Results. All our numerical examples are based on the operator $A_k = 1/2 + K_k + i n V_k$, where the coupling parameter is $\eta = k$ or $\eta = 1$. The ansatz spaces $X_N$ are taken to be standard $hp$-BEM spaces of piecewise polynomials of degree $p$. Specifically, let $T = \{K_i \mid i = 1, \ldots, N\}$ be a partition of $\Gamma$ into $N$ elements and let $F_K : [-1,1] \to \Gamma$ be the element maps. Then $S^p(T) = \{u \in L^2(\Gamma) \mid u|_{K} \circ F_K \in \mathcal{P}_p \ \forall K \in T\}$. Here, $\mathcal{P}_p$ denotes the univariate polynomials of degree $p$. The element maps $F_K$ are constructed as described in Example 3.13, i.e., the uniform mesh $\hat{T}$ in parameter space is transported to the curve $\Gamma$ by its parametrization. The basis of $S^p(T)$ selected for the computations is taken to be the push-forward of the $L^2$-normalized Legendre polynomials on the reference element $[-1,1]$. The BEM operators $K'$ and $V$ are set up with an $hp$-quadrature with $p_{max}+2$ quadrature points in each direction per quadrature cell (usually, $p_{max} = 20$). Details of the fast quadrature technique employed are described in [11]. Systematically, the number of elements $N$ is taken proportional to $k$.

Denoting by $P_{T,p} : L^2(\Gamma) \to S^p(T)$ the Galerkin projector, which is characterized by

$$a_T^p(u - P_{T,p}u, v) = 0 \quad \forall v \in S^p(T),$$

we approximate the Galerkin error $\|Id - P_{T,p}\|_{L^2\rightarrow L^2}$ by the formula

$$\|Id - P_{T,p}\|_{L^2\rightarrow L^2} \approx \sup_{0 \neq v \in S^{p_{max}}(T)} \frac{\|v - P_{T,p}v\|_{L^2}}{\|v\|_{L^2}}. \quad (4.1)$$

Unless stated otherwise, we select $p_{max} = 20$ for the computation of (4.1). Since for smooth domains we may expect the quasi-optimality constant to be asymptotically 1 (see the discussion in Section 5 below) we do not present in our numerical examples $\|Id - P_{T,p}\|_{L^2\rightarrow L^2}$ of (4.1) but instead the Galerkin Error Measure

$$E := \sqrt{\|Id - P_{T,p}\|_{L^2\rightarrow L^2}^2}. \quad (4.2)$$

We also report the extremal singular values $\sigma_{min}(M^{-1}A')$ and $\sigma_{max}(M^{-1}A')$ for $p = 10$, where $M$ denotes the mass matrix for the space $S^p(T)$ and $A'$ represents the stiffness matrix for the discretization of $A_k'$. These numbers give a very good indication of $1/\|A_k'\|_{L^2\rightarrow L^2}$ and $\|A_k'\|_{L^2\rightarrow L^2}$. The singular values are computed with the LAPACK-routine zgesvd.

The examples below are selected to illustrate the theoretical results of the paper and to test its limits. The geometries of Examples 4.1 and 4.2 are a circle and an ellipse and hence fully covered by our theory (recall that $C(A_k,0,k) = C(A_k,0,k,0) = O(1)$ by [7]). The geometries in Examples 4.3, 4.4, 4.5, 4.6 are no longer star-shaped so that bounds for $C(A_k,0,k) = C(A_k,0,k,0) = O(1)$ are not known. In Examples 4.5, 4.6 we even leave the realm of smooth geometries; in the terminology of [5, Thm. 5.1] these geometries are “trapping domains” and the wavenumbers selected in our computations are precisely the critical wavenumbers identified there. Clearly, the choice of the coupling parameter $\eta$ in (1.4) affects the norm $C(A_k,0,k)$ and thus, in turn, the conditions on the approximation properties of the discrete spaces $X_N$ for quasi-optimality. We therefore also perform calculations for the choice $\eta = 1$ in Examples 4.4 and 4.6.

**Example 4.1.** $\Omega = B_1(0)$ is a circle with radius $r = 1$. The mesh has $N = k$ elements of equal size. The element maps $F_K$ are obtained with the aid of the parameterization $\{(r \cos \varphi, r \sin \varphi) \mid \varphi \in [0,2\pi]\}$ of the circle. The coupling parameter $\eta$ is selected as
Fig. 4.1. (see Example 4.1) Circle with radius \( r = 1 \), \( \eta = k \). Left: Galerkin Error Measure \( E \) (see (4.2)). Right: Estimate of \( \|A'_k\|_{L^2-L^2} \) and \( 1/\|A'_k\|_{L^2-L^2} \).

\[
\begin{array}{|c|c|c|}
\hline
k & \sigma_{\text{max}}(M^{-1}A') & \sigma_{\text{min}}(M^{-1}A') \\
\hline
4 & 1.26835 & 0.5 \\
8 & 1.54632 & 0.5 \\
16 & 1.80880 & 0.5 \\
32 & 2.40042 & 0.5 \\
64 & 2.98223 & 0.5 \\
128 & 3.76487 & 0.5 \\
256 & 4.73099 & 0.5 \\
1024 & 7.48469 & 0.5 \\
\hline
\end{array}
\]

Fig. 4.2. (see Example 4.2) Ellipse with semi-axes \( a = 1 \) and \( b = 1/4 \). Left: Galerkin Error Measure \( E \) (see (4.2)). Right: Estimate of \( \|A'_k\|_{L^2-L^2} \) and \( 1/\|A'_k\|_{L^2-L^2} \).

\[
\begin{array}{|c|c|c|}
\hline
k & \sigma_{\text{max}}(M^{-1}A') & \sigma_{\text{min}}(M^{-1}A') \\
\hline
4 & 1.41593 & 0.489 \\
8 & 1.71889 & 0.5 \\
16 & 2.01108 & 0.5 \\
32 & 2.64065 & 0.5 \\
64 & 3.43955 & 0.5 \\
128 & 4.57966 & 0.5 \\
256 & 6.0845 & 0.5 \\
\hline
\end{array}
\]

\( \eta = k \). Fig. 4.1 shows the Galerkin Error Measure of (4.2) as a function of \( p \); we also give an indication of \( \|A'_k\|_{L^2-L^2} \) and \( 1/\|A'_k\|_{L^2-L^2} \).

**Example 4.2.** \( \Omega \) is an ellipse with semi-axes \( a = 1 \) and \( b = 1/4 \). The boundary \( \Gamma \) is parametrized in the standard way by \( \{(a \cos \varphi, b \sin \varphi) \mid \varphi \in [0, 2\pi)\} \). The element maps are obtained by uniformly subdividing the parameter interval \( [0, 2\pi) \), and the mesh has \( N = k \) elements. The coupling parameter \( \eta \) is \( \eta = k \). The numerical results are presented in Fig. 4.2.

**Example 4.3.** \( \Omega = B_{1/2}(0) \setminus \overline{B_{1/4}(0)} \) is the annular region between two circles of radii 1/2 and 1/4. The normal vector appearing in the definition of \( K'_k \) always points outwards. The boundary \( \partial \Omega \) is parametrized in the standard way with polar coordinates. The wave number is related to the number of elements \( N \) by \( N = 2k \), and each of the two components of connectedness of \( \partial \Omega \) has \( N/2 \) elements. The coupling parameter \( \eta \) is \( \eta = k \). The results can be found in Fig. 4.3.

**Example 4.4.** The setup is as in Example 4.3 with coupling parameter \( \eta = 1 \) instead of \( \eta = k \). The result are presented in Fig. 4.4.
Example 4.5. $\Omega$ is the $C$-shaped domain given by

$$\Omega = ((-r/3,r/3) \times (-r/2, r/2)) \setminus ((0,r/3) \times (-r/6, r/6)), \quad r = 1/2.$$ 

For different values of the parameter $m \in 3\mathbb{N}$, we select the number of elements $N$ and the wavenumber $k$ according to

$$N = 20m, \quad k = \frac{3\pi}{r}.$$ 

The meshes are uniform on $\Gamma$. The coupling parameter is $\eta = k$. The results can be found in Fig. 4.5.

Example 4.6. The setup is the same as in Example 4.5 with the exception that the coupling parameter $\eta$ is chosen as $\eta = 1$ instead of $\eta = k$ and that $p_{\text{max}} = 15$ instead of $p_{\text{max}} = 20$. The numerical results can be found in Fig. 4.6.

Discussion of the Numerical Examples.

1. We recall that in all numerical examples the mesh size $h$ is proportional to $1/k$. In the calculations based on smooth geometries, i.e., Examples 4.1,
4.2, 4.3, 4.4, we observe that the Galerkin Error Measure $E$ tends to zero as $p \to \infty$. This shows that indeed, asymptotically, the quasi-optimality constant is 1. Closer inspection of the numerical results indicates an $O(1/p)$-behavior, which is consistent with the finite shift properties of $V_0$ and $K'_0$. It is noteworthy that in Example 4.4, where $\eta = 1$ the asymptotic behavior of the Galerkin Error Measure appears to be $O(1/(pk))$. Hence, for that geometry, the combined $\eta$ and $k$ dependence appears to be $O((1 + |\eta|)/(kp))$.

2. In the case of a circle (Example 4.1), an ellipse (Example 4.2), and the case of an annular geometry with coupling parameter $\eta = k$ (Example 4.3) we observe that the condition

$$\frac{kh}{p} \text{ sufficiently small} \quad (4.3)$$

is already enough to ensure quasi-optimality of the Galerkin $hp$-BEM. The side condition $p = O(\log k)$ of (1.1) is not visible. For the special case of a circle, this absence of “pollution” may be expected in view the analysis of [2].

3. The C-shaped geometry in the Examples 4.5, 4.6 is not smooth. Hence, the
operator $K'_k$ is no longer smoothing and one cannot expect the Galerkin Error Measure $E$ of (4.2) to tend to zero. This is indeed visible in Figs. 4.5, 4.6. The sharp decrease of the the Galerkin Error Measure $E$ for large $p$ is likely to be a numerical artefact since $E$ is obtained by comparing lower values of $p$ with the result for $p_{\text{max}} = 20$ in the case of Fig. 4.5 and $p_{\text{max}} = 15$ in Fig. 4.6.

4. The work [7] shows that $C(A'_k, 0, k) = \|(A'_k)^{-1}\|_{L^2 - L^2}$ is bounded uniformly in $k$ for star-shaped geometries. Indeed, the numerical results for the case of a circle (Example 4.1) and an ellipse (Example 4.2) confirm this. In contrast, the geometries of Examples 4.3 and 4.5 are not star-shaped and we observe in Figs. 4.3, 4.4, 4.5, 4.6 that $C(A'_k, 0, k)$ is not bounded uniformly in $k$ but grows algebraically. The norm $\|A'_k\|_{L^2 - L^2}$ is seen to grow (mildly) in $k$ in all examples. This is in accordance with known results. For example, [9] shows $\|A'_k\|_{L^2 - L^2} = O(k^{1/3})$ for the case of a circle and [5] proves $\|A'_k\|_{L^2 - L^2} = O(k^{1/2})$ for general 2D Lipschitz domains. For the convenience of the reader, we present the tables of Figs. 4.1–4.6 in the form of graphs in Fig. 4.7.

5. For the C-shaped geometry of Examples 4.5, 4.6, a lower bound for $C(A'_k, 0, k)$ is given in [5, Thm. 5.1] as

$$C(A'_k, 0, k) \geq Ck^{9/10} \left(1 + \left[\frac{\eta}{k}\right]\right)^{-1}.$$ 

We observe in particular that selecting $\eta = O(1)$ instead of $\eta = O(k)$ leads to an increase of the bound by a factor $k$. Our numerical examples (see the tables in Figs. 4.5, 4.6 or the graphs in Fig. 4.7) indicate that the lower bounds of [5, Thm. 5.1] are essentially sharp.

6. In the case of circular/elliptic geometries and even in the case of the non-convex geometry of an annulus, we did not observe a “pollution” effect; in other words, quasi-optimality of the Galerkin BEM takes place as soon as $kh/p$ is sufficiently small. The more stringent scale resolution condition (1.1) that stipulates $p = O(\log k)$ might, however, be needed in more general situations. This is the purpose of selecting $\eta = 1$ in the Examples 4.4, 4.6. It has the effect of increasing $C(A'_k, 0, k)$, which, according to the analysis of Section 3, puts conditions on the approximation properties of the $hp$-BEM spaces. Indeed, the plots in Figs. 4.4, 4.6 indicate that the condition “$kh/p$ small” alone is insufficient to ensure quasi-optimality of the Galerkin BEM.

5. concluding remarks. Our convergence theory rests on the stability of the discretization of the operators $A_0$ and $A'_0$ given by (3.1), (3.2). In the present context of smooth geometries, it is possible select $A_0 = A'_0 = \frac{1}{2}\text{Id}$ and thus circumvent Assumption 3.4. The key argument is Lemma 5.1 below, which could then be used to show that Lemma 3.2 is valid almost verbatim (the powers of $k$ for the analytic contributions may change) with $A_0 = A'_0 = \frac{1}{2}\text{Id}$ instead of the expressions given in (3.1), (3.2). Nevertheless, we have not opted for this analytical development. The decompositions of Lemmata 2.1, 2.3 are based on decompositions of potentials defined on $\mathbb{R}^d \setminus \Gamma$ and then appropriate traces on $\Gamma$ are taken to infer decompositions of $A_k$, $A'_k$. With this technique, the operators $\frac{1}{2} + K_0$ and $\frac{1}{2} + K'_0$ appear quite naturally, and one may hope to be able to develop a decomposition theory (and then in turn a convergence theory) for problems with piecewise smooth geometries. In contrast, the decomposition of $K_0$ of Lemma 5.1 below rests heavily on the smoothness of $\Gamma$, and it is not clear that a generalization to non-smooth geometries could at all be possible.
Fig. 4.7. Extremal singular values of $M^{-1}A'$ for Examples 4.1 (top left), 4.2 (top right), 4.3 (middle left), 4.4 (middle right), 4.5 (bottom left), 4.6 (bottom right).

**Lemma 5.1.** Let $\Gamma$ be analytic. Let $q \in (0, 1)$. Then the operators $A_k$ and $A'_k$ can be decomposed as

$$A_k = \frac{1}{2} + R_A + k[\tilde{A}_A], \quad A'_k = \frac{1}{2} + R_{A'} + k[\tilde{A}_{A',1}] + [\partial_n \tilde{A}_{A',2}].$$
where for constants $C, \gamma > 0$ and a tubular neighborhood $T$ of $\Gamma$, which are all independent of $k \geq k_0$:

\[
\|R_A\|_{H^1(\Gamma) \rightarrow L^2(\Gamma)} \leq Ck, \quad \|R_A\|_{L^2(\Gamma) \rightarrow L^2(\Gamma)} \leq q, \\
\widetilde{A}_A \varphi \in \mathcal{A}(Ck^{\max\{1,d/2-1\}}\|\varphi\|_{L^2, \gamma, T \setminus \Gamma}) \quad \forall \varphi \in L^2(\Gamma), \\
\|R_A\|_{H^1(\Gamma) \rightarrow L^2(\Gamma)} \leq Ck, \quad \|R_A\|_{L^2(\Gamma) \rightarrow L^2(\Gamma)} \leq q, \\
\widetilde{A}_A \varphi \in \mathcal{A}(Ck^{\max\{1,d/2-1\}}\|\varphi\|_{L^2, \gamma, T \setminus \Gamma}) \quad \forall \varphi \in L^2(\Gamma), \quad i \in \{1, 2\}.
\]

**Proof.** The ingredient is a further decomposition of $K_0$ and $K'_0$ using the frequency splitting operators $H^{neg}_T$ and $L^{neg}_T$ of [16, Lemma 5.3]. We can write

\[
K_0 = H^{neg}_T K_0 + \gamma_{01} L^{neg}_T K_0, \quad K_0 = H^{neg}_T K'_0 + \gamma_{01} L^{neg}_T K'_0.
\]

Since $K_0 : L^2(\Gamma) \rightarrow H^1(\Gamma)$ and $K'_0 : L^2(\Gamma) \rightarrow H^1(\Gamma)$, we obtain from [16, Lemma 5.3] for arbitrary $q \in (0, 1)$

\[
\|H^{neg}_T K_0\|_{L^2 \rightarrow L^2} \leq Cq/k, \quad \|H^{neg}_T K'_0\|_{H^1 \rightarrow L^2} \leq C, \\
\|H^{neg}_T K'_0\|_{L^2 \rightarrow L^2} \leq Cq/k, \quad \|H^{neg}_T K'_0\|_{H^1 \rightarrow L^2} \leq C.
\]

For the analytic parts $L^{neg}_T K_0$ and $L^{neg}_T K'_0$, [16, Lemma 5.3] asserts the existence of a tubular neighborhood $T$ of $\Gamma$ and a constants $C, \gamma > 0$ (possibly depending on the choice of $q$) with

\[
\|\nabla^n L^{neg}_T K_0 f\|_{L^2(T)} \leq Ck^{d/2} \gamma^n \max\{n, k\}^n \|f\|_{L^2(\Gamma)} \quad \forall n \in \mathbb{N}_0, \\
\|\nabla^n L^{neg}_T K'_0 f\|_{L^2(T)} \leq Ck^{d/2} \gamma^n \max\{n, k\}^n \|f\|_{H^{-1/2}(\Gamma)} \quad \forall n \in \mathbb{N}_0.
\]

Combining these results with Lemmata 2.1, 2.3 leads to the desired statement. \(\square\)

**Appendix A. Proof of Theorem 3.11.** Proof of Theorem 3.11: We introduce the abbreviation $e := u - u_N$. Let $w_N \in X_N$ be arbitrary. Then by the triangle inequality

\[
\|e\|_0 \leq \|u - w_N\|_0 + \|u_N - w_N\|_0. \tag{A.1}
\]

Hence, we have to estimate $\|u_N - w_N\|_0$. By the discrete inf-sup condition we can find $v_N \in X_N$ with $\|v_N\|_0 = 1$ and $\gamma_0 \|u_N - w_N\|_0 \leq (A'_0(u_N - w_N), v_N)_0$. With the Galerkin orthogonality $(A'_0(u - u_N), v_N)_0 = 0$, we then produce

\[
\gamma_0 \|u_N - w_N\|_0 \leq ((A'_0 - A'_0) (u_N - w_N), v_N)_0 + (A'_0 (u_N - w_N), v_N)_0 \\
= ((A'_0 - A'_0) (u_N - w_N), v_N)_0 + (A'_0 (u - w_N), v_N)_0 \\
= ((A'_0 - A'_0)e, v_N)_0 + (A'_0 (u - w_N), v_N)_0 \\
\leq \|A'_0\|_{L^2 \rightarrow L^2} \|u - w_N\|_0 + (A'_0 - A'_0)e, v_N)_0. \tag{A.2}
\]

In order to treat the term $((A'_0 - A'_0)e, v_N)_0$ we define $\psi \in L^2(\Gamma)$ by

\[
((A'_0 - A'_0)z, v_N)_0 = (z, A_{-k} \psi)_0 \quad \forall z \in L^2(\Gamma). \tag{A.3}
\]

Lemma 3.2 tells us

\[
\psi = A_{-k}^{-1}(A_{-k} - A_0)v_N \tag{A.4}
\]
By selecting $z = e$ in (A.3), using Galerkin orthogonality satisfied by the error $e$ and orthogonality properties of $\Pi_N^2$ we obtain

\[
(A_k' - A_0')e, v_N)_0 = (e, A_{-k} \psi)_0 = (A_k' e, \psi - \Pi_N^2 \psi)_0 = (A_0' e, \psi - \Pi_N^2 \psi)_0 + ((A_k' - A_0')e, \psi - \Pi_N^2 \psi)_0
\]

Hence, from (A.4) and $\|v_N\|_0 = 1$

\[
|((A_k' - A_0')e, v_N)_0| \leq \left\{ \|A_0'\|_{L^2\rightarrow L^2} + \|((\Id - \Pi_N^2)(A_k' - A_0'))\|_{L^2\rightarrow L^2} \right\} \times \|((\Id - \Pi_N^2)A_{-k}^{-1}(A_{-k} - A_0'))\|_{L^2\rightarrow L^2} \|e\|_0.
\]

From Lemmata 3.6, 3.7 we get for arbitrary $q \in (0, 1)$

\[
|((A_k' - A_0')e, v_N)_0| \leq \left\{ \|A_0'\|_{L^2\rightarrow L^2} + q + C k \eta(N, k, \gamma) \right\} \times \left\{ q + C k \left( 1 + k^{5/2}{\|A_{-k}^{-1}\|_{L^2\rightarrow L^2}} \right) \eta_1(N, -k, \gamma) \right\} \|e\|_0.
\]

Select now $q \in (0, 1)$ such that $\|A_0'\|_{L^2\rightarrow L^2} + q < 1/2$. Then the constants $C$ and $\gamma$ in (A.5) are fixed and independent of $k$. We can furthermore select $\varepsilon > 0$ independent of $k$ such that the assumption (3.13) then guarantees that the product of the two curly braces in (A.5) is bounded by 1/2. Combining (A.1), (A.2), and (A.5) therefore yields

\[
\|e\|_0 \leq \left( 1 + \frac{\|A_0'\|_{L^2\rightarrow L^2}}{\gamma_0} \right) \|u - w_N\|_0 + \frac{1}{2}\|e\|_0,
\]

which leads to the desired estimate. \qed
