Time domain boundary integral equations and convolution quadrature for scattering by composite media

Alexander Rieder, Francisco-Javier Sayas, Jens Markus Melenk

October 28, 2020

We consider acoustic scattering in heterogeneous media with piecewise constant wave number. The discretization is carried out using a Galerkin boundary element method in space and Runge-Kutta convolution quadrature in time. We prove well-posedness of the scheme and provide a priori estimates for the convergence in space and time.

1 Introduction

A basic problem in wave propagation is that of scattering in heterogeneous media. A prominent example is the classical inverse problem of seismic analysis, where one aims at understanding the structure of a medium from the scattered fields of impinging waves. Such an analysis requires efficient methods for the so-called forward problem, in which the heterogeneous medium is assumed given and the scattering field of impinging waves is computed. In this setting, an important problem class, which is considered in the present work, is that of piecewise homogeneous media.

When considering piecewise constant material parameters, time domain boundary integral equations (TDBIE) can be applied since fundamental solutions for the wave equation are available. A particular strength of boundary integral techniques is that they allow for a convenient treatment of unbounded domains, which appear frequently in scattering problems.

In order to treat the scattering from heterogeneous media embedded in an unbounded homogeneous medium, there are in fact several possibilities. One of the more common approaches is to combine the boundary element method in the exterior with a finite element method for a bounded domain. This approach was taken in [BLS15b] and [HS16]. For the Schrödinger equation, a similar approach was investigated in [MR17]. [AJRT11] combines a discontinuous Galerkin method with a boundary element method. Another approach that is suitable for the case of piecewise constant material properties is to use boundary integral equations for each subdomain and suitably couple them. In the
context of time-harmonic scattering this approach has been pioneered by Costabel and Stephan [CS85] in the case of a single scatterer and by von Petersdorff for multiple scatterers [vP89]. These approaches have later been extended in [CH13, Cla11, HJH12]. The case of time-dependent scattering has thus far seen less attention, although the case of a single scatterer embedded in a homogeneous medium was treated in [QS16].

For the discretization of the time variable, a variety of approaches have been developed in the past. The oldest one is based on a space-time formulation involving the retarded potentials, [BHD86a, BHD86b, GMO+18]. Another common approach is based on Lubich’s convolution quadrature [Lub88a, Lub88b] (CQ) and its Runge-Kutta variation (RK-CQ), introduced in [LO93]. The present work takes this route and analyzes an RK-CQ.

In the treatment of TDBIEs using CQ methods the case of scattering by a single impenetrable obstacle (using different boundary conditions to account for different material behaviors) has garnered a lot of attention, and the available numerical methods can be considered well developed, see [BS09, BLS15a, DS13] and the comprehensive treatment in [Say16]. Recently, these methods have even been extended to a class of nonlinear scattering problems, see [BR18, BL19].

In this paper, we present and analyze a fully discrete formulation of the multiple-subdomain acoustic scattering problem based on a Galerkin boundary element method and RK-CQ for the time discretization. Our analysis is based on a pure time-domain point of view, combining ideas by [BLS15a] and [HQS17] with the theory of Runge-Kutta approximations of abstract semigroups, as laid out in [AMP03] and recently extended in [RSM20]. A main contribution of the present work is that our analysis covers scattering problems by piecewise constant materials with a very general layout of subdomains. Most notably, in comparison to [QS16] we allow for more than one subdomain and permit cross points where more than two subdomains touch. Our approach therefore generalizes the results of [Qiu16, Chapters 3 and 4], which only allows certain nested geometries (see Section 5). Compared to other works, e.g., [QS16, Qiu16] we also consider RK-CQ using the novel time-domain analysis developed in [RSM20], whereas previous analyses concentrated on multistep methods, whose order, however, is limited to 2 if A-stability is required. These higher order RK-methods suffer from some reduction of order phenomenon in that the convergence order falls somewhere between the stage- and classical order of the RK-method. By careful analysis of the regularity of certain lifting problems, we are able to establish an improved convergence by $k^{1/2}$ compared to a more straightforward analysis, as long as the mild assumption is made that the incident wave is in $L^2(\partial \Omega_0)$.

We analyze several RK-CQ formulations for a scattering problem. For a slightly non-standard formulation based on differentiating the Dirichlet data we show that a higher order of convergence can be achieved than for the more standard one based on using same order of differentiation of the Dirichlet and Neumann data.

Related to our approach is the recent [EFHS19], which studies, on the continuous level, well-posedness of certain TDBIEs for acoustic scattering problems. [EFHS19] considers the case of two subdomains (plus the exterior) endowed with suitable transmission conditions and general boundary conditions. Their approach relies on frequency domain
estimates. In contrast, our analysis includes a fully discrete convergence analysis for more complicated geometric situations of arbitrary number of subdomains. In order to do so, we use the novel “time-domain only approach” developed along side this paper and presented recently in [RSM20], showcasing that this approach is feasible for complex model problems that go beyond rather simple ones.

The paper is structured as follows. In Section 2 we present the details of the model problem under consideration. We reformulate the problem in the language of $C_0$-semigroups and prove well-posedness. (In order to streamline the presentation, all this is done in a semidiscrete setting that takes into account the Galerkin discretization in space). Section 3 presents a boundary integral formulation and establishes equivalence in the fully continuous and semidiscrete settings. Section 4 deals with the discretization of the time-variable using Runge-Kutta based convolution quadrature and gives the final fully discrete scheme for the scattering problem. We give explicit error bounds for the convergence in space and time. Section 5 relates our results to the existing literature by showing equivalences in certain simpler geometric situations. In Section 6 we give numerical examples in 2D.

We close with a remark on notation. Throughout this article we will encounter collections of functions on different levels. Functions defined on a single subdomain will be denoted by regular lowercase characters. For collections of such functions for multiple subdomains, we will use bold characters. When discretizing in time using an $m$-stage Runge-Kutta method, we will add the superscript $k$ to all quantities. For each scalar quantity, we obtain a stage vector of $m$ functions. These will be denoted by uppercase letters, the corresponding (scalar) approximations at the time-steps will then again be the same lowercase letter. For example, starting from scalar functions $u_\ell$ on $\Omega_\ell$, collecting them gives $\mathbf{u} := (u_\ell)_{\ell=0}^L$. The stage vector of their RK-approximation is then $\mathbf{U}^k$ and the scalar approximation will be $u^k$. The same rules will be applied to functions defined on the boundary of subdomains, except that we will use the Greek alphabet.

## 2 Model problem and notation

We consider the scattering of waves from one or multiple objects, with possibly adjacent parts and different material properties. We are given mutually disjoint bounded Lipschitz domains $\Omega_\ell \subseteq \mathbb{R}^d$, $\ell = 1, \ldots, L$, and we use

$$\Omega_0 := \mathbb{R}^d \setminus \bigcup_{\ell=1}^L \overline{\Omega_\ell}, \quad \Gamma := \bigcup_{\ell=1}^L \partial \Omega_\ell,$$

to respectively denote the unbounded exterior domain (which might be disconnected) and the union of the boundaries of all the domains. In physical terms, the scatterer occupies the closed set $\bigcup_{\ell=1}^L \overline{\Omega_\ell}$, while $\Omega_0$ is the surrounding medium. The set $\Gamma$ will be called the skeleton of the partition of the scatterer. The acoustic behavior of the surrounding domain and the scatterer is described with two piecewise constant positive functions $\kappa, c : \mathbb{R}^d \to (0, \infty)$ given by

$$\kappa|_{\Omega_\ell} \equiv \kappa_\ell > 0, \quad c|_{\Omega_\ell} \equiv c_\ell > 0, \quad \ell = 0, \ldots, L.$$
2.1 The scattering problem

We now give the formal definition of the model problem. We will later on encounter other, equivalent, formulations. We start with an incident wave. Generally thinking of transient plane waves, we assume that we are given a sufficiently smooth function $u^{\text{inc}} : \mathbb{R} \to H^1_{\text{loc}}(\Omega_0)$ such that

$$c^{-2}u^{\text{inc}}(t) = \kappa_0 \Delta u^{\text{inc}}(t) \quad \forall t \in \mathbb{R}, \quad (2.1a)$$

$$\text{supp } u^{\text{inc}}(t) \subseteq \Omega_0 \quad \forall t \leq 0. \quad (2.1b)$$

(For cylindrical or spherical incident waves, a source term, supported strictly in $\Omega_0$, has to be added in (2.1a).) The total wave field is then a function $u^{\text{tot}} : \mathbb{R} \to H^1_{\text{loc}}(\mathbb{R}^d)$ satisfying

$$c^{-2}u^{\text{tot}}(t) = \nabla \cdot (\kappa \nabla u^{\text{tot}})(t) \quad \forall t \in \mathbb{R}, \quad (2.2a)$$

$$u^{\text{tot}}(t) = u^{\text{inc}}(t) \quad \text{in } \Omega_0, \quad \forall t \leq 0, \quad (2.2b)$$

$$\kappa \nabla (u^{\text{tot}} - u^{\text{inc}})(t) \text{ is bounded } \forall t \in \mathbb{R}. \quad (2.2c)$$

The condition $u^{\text{tot}}(t) \in H^1_{\text{loc}}(\mathbb{R}^d)$ implies that the traces of $u^{\text{tot}}(t)$ do not jump across $\Gamma$. The fact that we are applying the divergence operator to $\kappa \nabla u^{\text{tot}}(t)$ in $\mathbb{R}^d$ implies that the normal components of $\kappa \nabla u^{\text{tot}}(t)$ do not jump across $\Gamma$.

We will write the problem in terms of the scattered wave $u := u^{\text{tot}} - u^{\text{inc}}$ and restricted to the time interval $[0, \infty)$. The vanishing values of $u$ for negative times will make a reappearance once the retarded potentials are introduced. To introduce this formulation, while avoiding to deal with the possibly complicated forms for the intersections of the boundaries of the subdomains $\Omega_\ell$, we proceed as follows. We first extend $u^{\text{inc}}$ to the equally named function $u^{\text{inc}} : [0, \infty) \to L^2(\mathbb{R}^d)$ by setting $u^{\text{inc}}(t) \equiv 0$ in $\mathbb{R}^d \setminus \Omega_0$ for all $t$. This is mostly for notational convenience, as it allows us to write the equations for $u^{\text{tot}} = u + u^{\text{inc}}$ in a concise way such as in (2.2) below. To that end, we introduce an arbitrary open ball $B$ that contains the skeleton $\Gamma$. The scattered field is then a function $u : [0, \infty) \to H^1(\mathbb{R}^d \setminus \Gamma)$ satisfying

$$c^{-2}u(t) = \nabla \cdot (\kappa \nabla u)(t) \quad \text{in } \mathbb{R}^d \setminus \Gamma \quad \forall t \geq 0, \quad (2.2a)$$

$$u(t) + u^{\text{inc}}(t) \in H^1(B) \quad \forall t \geq 0, \quad (2.2b)$$

$$\kappa \nabla (u(t) + u^{\text{inc}}(t)) \in H(\text{div}, B) \quad \forall t \geq 0, \quad (2.2c)$$
with vanishing initial conditions

\[ u(0) = 0, \quad \dot{u}(0) = 0. \quad (2.2d) \]

### 2.2 A multiply overlapped wave problem

In this section we will formulate a generalization of problem (2.2) including some sort of partial observation of transmission conditions on the skeleton. We will end up having \( L + 1 \) fields \( u_0, \ldots, u_L \), where \( u_\ell|_{\Omega_\ell} \) will be, in a sense to be made precise later, an approximation of \( u|_{\Omega_\ell} \). The transmission conditions implicit in equations (2.2b) and (2.2c) will be relaxed and, at the same time, given a trace operator-based formulation. A rigorous formulation of the problem will use a considerable collection of spaces and operators, which we now introduce:

1. **Trace operators**

\[ \gamma_{\ell}^{\text{int}}, \gamma_{\ell}^{\text{ext}}, \{\{\gamma_{\ell} \cdot \}\} : H^1(\mathbb{R}^d \setminus \partial \Omega_\ell) \rightarrow H^{1/2}(\partial \Omega_\ell), \]

where the interior and exterior traces are self-explanatory (note that for \( \partial \Omega_0 \), the interior trace is taken from the unbounded domain \( \Omega_0 \)) and

\[ \{\{\gamma_{\ell} u\} := \frac{1}{2}(\gamma_{\ell}^{\text{int}} u + \gamma_{\ell}^{\text{ext}} u). \]

2. **Weak normal trace operators**

\[ \gamma_{\nu,\ell}^{\text{int}}, \gamma_{\nu,\ell}^{\text{ext}}, \{\{\gamma_{\nu,\ell} \cdot \}\} : H(\text{div}, \mathbb{R}^d \setminus \partial \Omega_\ell) \rightarrow H^{-1/2}(\partial \Omega_\ell), \]

defined similarly with, e.g., \( \gamma_{\nu,\ell}^{\text{int}} u = \nu \cdot u_{\ell}|_{\Omega_\ell} \) for sufficiently smooth \( u \) and noting that the normal is always taken to point out of the corresponding domain \( \Omega_\ell \).

3. **Four spaces collecting \( L + 1 \) fields (scalar or vector-valued) on \( \mathbb{R}^d \setminus \partial \Omega_\ell \),**

\[
\mathcal{H}^{\text{div}} := \prod_{\ell=0}^L H(\text{div}, \mathbb{R}^d \setminus \partial \Omega_\ell), \quad \mathcal{H} := \prod_{\ell=0}^L H^1(\mathbb{R}^d \setminus \partial \Omega_\ell),
\]

\[
\mathcal{H}^{-1/2}_{\Gamma} := \prod_{\ell=0}^L H^{-1/2}(\partial \Omega_\ell), \quad \mathcal{H}^{1/2}_{\Gamma} := \prod_{\ell=0}^L H^{1/2}(\partial \Omega_\ell),
\]

endowed with the product norms. The \( \mathcal{H}^{-1/2}_{\Gamma} \times \mathcal{H}^{1/2}_{\Gamma} \) duality will be denoted \( \langle \cdot, \cdot \rangle_{\Gamma} \). It extends the usual \( L^2 \) inner product, i.e., for \( u = (u_\ell)_{\ell=0}^L \) and \( v = (v_\ell)_{\ell=0}^L \) in \( \prod_{\ell=0}^L L^2(\partial \Omega_\ell) \), it is given by

\[
\langle u, v \rangle_{\Gamma} := \sum_{\ell=0}^L \int_{\partial \Omega_\ell} u_\ell v_\ell.
\]
4. Diagonal operators

\[ \gamma_{\text{int}}, \gamma_{\text{ext}}, [\gamma], \{\{\gamma\}\} : \mathcal{H} \to \mathcal{H}_{1/2}^{\Gamma}, \]

\[ \gamma_{\nu}^{\text{int}}, \gamma_{\nu}^{\text{ext}}, [\gamma_{\nu}], \{\{\gamma_{\nu}\}\} : \mathcal{H}_{\text{div}} \to \mathcal{H}_{-1/2}^{\Gamma}. \]

5. Single-trace spaces

\[ \mathcal{Y} := \{ (\gamma_{\ell}^{\text{int}} u)_{\ell=0}^{L} : u \in H^{1}(\mathbb{R}^{d}) \} \]

\[ = \{ \psi \in \mathcal{H}_{1/2}^{\Gamma} : \exists u \in H^{1}(\mathbb{R}^{d}), \psi = \gamma_{\text{int}} u \}, \]

\[ \mathcal{X} := \{ (\gamma_{\nu}^{\text{int}} v)_{\ell=0}^{L} : v \in H(\text{div}, \mathbb{R}^{d}) \} \]

\[ = \{ \phi \in \mathcal{H}_{-1/2}^{\Gamma} : \exists v \in H(\text{div}, \mathbb{R}^{d}), \phi = \gamma_{\nu}^{\text{int}} v \}, \]

which are closed subspaces of \( \mathcal{H}_{1/2}^{\Gamma} \) and \( \mathcal{H}_{-1/2}^{\Gamma} \) respectively.

While the problem is posed on the “broken” spaces \( \mathcal{H} \) and \( \mathcal{H}_{\text{div}} \), the spaces \( \mathcal{X} \) and \( \mathcal{Y} \) are introduced to enforce continuity conditions across interfaces \( \partial \Omega_{i} \cap \partial \Omega_{k} \); see Figure 2.1c. This is done following the ideas of \([\text{vP89}]\), but using notation analogous to \([\text{CH13}]\). Note the slight abuse of notation in the second definition of both spaces, where the diagonal trace operators are used on a single function, which is assumed to be copied \( L + 1 \) times.

**Lemma 2.1** (Restricting and gluing). If \( \mathbf{u} = (u_{\ell})_{\ell=0}^{L} \in \mathcal{H} \) satisfies \([\gamma \mathbf{u}] \in \mathcal{Y} \) and \( \gamma^{\text{ext}} \mathbf{u} \in \mathcal{Y} \), then the function \( u : \mathbb{R}^{d} \to \mathbb{R} \) defined by \( u|_{\Omega_{i}} := u_{\ell}|_{\Omega_{i}} \) satisfies \( u \in H^{1}(\mathbb{R}^{d}) \). Similarly, if \( \mathbf{v} = (v_{\ell})_{\ell=0}^{L} \in \mathcal{H}_{\text{div}} \) satisfies \([\gamma_{\ell} \mathbf{v}] \in \mathcal{X} \) and \( \gamma_{\ell}^{\text{ext}} \mathbf{v} \in \mathcal{X} \), then the function \( v : \mathbb{R}^{d} \to \mathbb{R} \) defined by \( v|_{\Omega_{i}} := v_{\ell}|_{\Omega_{i}} \) satisfies \( v \in H(\text{div}, \mathbb{R}^{d}) \).

**Proof.** The conditions imply \( \gamma^{\text{int}} \mathbf{u} \in \mathcal{Y} \) and \( \gamma_{\nu} \mathbf{v} \in \mathcal{X} \), from where the result follows using the definition of \( \mathcal{Y} \) and \( \mathcal{X} \). □

We now take two closed subspaces \( \mathcal{X}_{h} \subseteq \mathcal{X} \) and \( \mathcal{Y}_{h} \subseteq \mathcal{Y} \). When \( \mathcal{X}_{h} \) and \( \mathcal{Y}_{h} \) are finite dimensional they will play the role of approximation spaces for a Galerkin semidiscretization in space of an equivalent time domain boundary integral formulation. In order to succinctly write down Galerkin orthogonalities, we define the polar sets

\[ \mathcal{X}_{h}^{\circ} := \{ \psi \in \mathcal{H}_{1/2}^{\Gamma} : \langle \mu, \psi \rangle_{\Gamma} = 0 \ \forall \mu \in \mathcal{X}_{h} \}, \]

\[ \mathcal{Y}_{h}^{\circ} := \{ \phi \in \mathcal{H}_{-1/2}^{\Gamma} : \langle \phi, \eta \rangle_{\Gamma} = 0 \ \forall \eta \in \mathcal{Y}_{h} \}. \]

When \( \mathcal{X}_{h} = \mathcal{X} \) and \( \mathcal{Y}_{h} = \mathcal{Y} \) it can be proved (see [Cla11, Prop. 2.1]) that \( \mathcal{X}^{\circ} = \mathcal{Y} \) and \( \mathcal{Y}^{\circ} = \mathcal{X} \). In particular

\[ \langle \phi, \psi \rangle_{\Gamma} = 0 \ \forall \psi \in \mathcal{Y}, \ \phi \in \mathcal{X}. \]  

(2.4)

This also implies that \( \mathcal{X}_{h} \subseteq \mathcal{X} = \mathcal{Y}^{\circ} \subseteq \mathcal{Y}_{h}^{\circ} \) and likewise \( \mathcal{Y}_{h} \subseteq \mathcal{X}_{h}^{\circ} \).

We are finally ready to introduce the multiply overlapped transmission problem that is the object of the first part of this work. The data are functions \( \xi_{0} : [0, \infty) \to \mathcal{H}_{1/2}^{\Gamma} \)
and $\xi^1 : [0, \infty) \to H^{-1/2}_\Gamma$ and we look for $u^h = (u^h_\ell)_{\ell=0}^L : [0, \infty) \to H$ and $w^h = (w^h_\ell)_{\ell=0}^L : [0, \infty) \to H^{\text{div}}$ satisfying the first order system

$$
\dot{u}^h_\ell(t) = c_2^2 \nabla \cdot w^h_\ell(t), \quad \dot{w}^h_\ell(t) = \kappa_\ell \nabla u^h_\ell(t), \quad \forall t > 0, \quad \ell = 0, \ldots, L \tag{2.5a}
$$

(the differential operators in space are distributional derivatives in $\mathbb{R}^d \setminus \partial \Omega_\ell$), four transmission conditions for all $t \geq 0$

$$
\|\gamma u^h\|(t) + \xi^0(t) \in \mathcal{Y}_h, \quad \|\gamma^0 w^h\|(t) + \xi^1(t) \in \mathcal{X}_h, \tag{2.5b}
$$

$$
\gamma^\text{ext} u^h(t) \in \mathcal{X}^0_h, \quad \gamma^\text{ext} w^h(t) \in \mathcal{Y}^0_h, \tag{2.5c}
$$

and vanishing initial conditions

$$
u^h(0) = 0, \quad w^h(0) = 0. \tag{2.5d}
$$

The following result clarifies the relation between (2.5) and (2.2). In what follows we will write

$$(\partial_t^{-1} f)(t) := \int_0^t f(\tau) d\tau,
$$

with integration in the sense of Bochner in the space where $f$ takes values. The characteristic function of the domain $\Omega_\ell$ will be denoted $\chi_{\Omega_\ell}$. Before we state the result, and foreseeing possible confusion with notation in existing literature, let us emphasize that the interior traces from the unbounded domain $\Omega_0$ are coming from inside this domain and the normal vector points towards the scatterer in this case.

**Proposition 2.2.** Let

$$\xi^0 := (\rho^\text{int} u^\text{inc}, 0, \ldots, 0), \quad \xi^1 := (\kappa_0 \rho^\text{int} \nabla \partial^{-1}_t u^\text{inc}, 0, \ldots, 0).$$

If $(u^h, w^h)$ is a solution to (2.5) for the choice $\mathcal{X}_h = \mathcal{X}$, $\mathcal{Y}_h = \mathcal{Y}$, then $u : [0, \infty) \to H^1(\mathbb{R}^d \setminus \Gamma)$ defined by $u(t)|_{\Omega_\ell} := u^\ell_h(t)|_{\Omega_\ell}$ for all $t \geq 0$ and $\ell \in \{0, \ldots, L\}$ is a solution to (2.2). Reciprocally, if $u$ solves (2.2) and we define

$$u^\ell_h := \chi_{\Omega_\ell} u, \quad w^\ell_h := \kappa_\ell \nabla \partial^{-1}_t u^\ell_h, \quad \ell = 0, \ldots, L,$
$$

then $(u^h_{\ell=0}, (w^h_\ell)_{\ell=0}^L)$ is a solution to (2.5).

**Proof.** We only show that if $(u^h, w^h)$ is a solution to (2.5), then we can reconstruct a solution $u$ to (2.2) by setting $u|_{\Omega_\ell} = u^\ell_h$. On each subdomain $\Omega_\ell$, differentiating the first equality in (2.5a) and inserting the second one gives:

$$\dot{u}^\ell_h = c_2^2 \nabla \cdot \dot{w}^\ell_h = c_2^2 \nabla \cdot (\kappa_\ell \nabla u^\ell_h).$$

Thus, the reconstructed $u$ solves the PDE in $\mathbb{R}^d \setminus \Gamma$. To see the jump condition (2.2b), we consider the function $\tilde{u}^\ell_h := u^\ell_h + u^\text{inc} \chi_B$, where $\chi_B$ is a cutoff function with compact support which is equal to 1 in the ball of (2.2b), and the functions $\tilde{w}^\ell_h := w^\ell_h$ for $\ell \geq 1$. By (2.5b) and (2.5c), we can apply Lemma 2.1 to see that the reconstructed function $\tilde{u}$ defined by $\tilde{u}|_{\Omega_\ell} := \dot{u}_\ell$ is in $H^1(\mathbb{R}^d)$. Since $u + u^\text{inc}$ and $\tilde{u}$ coincide on the ball $B$ the jump condition (2.2b) follows. An analogous computation shows (2.2c).
2.3 A particular construction of the approximation spaces

Consider the two or three dimensional case, i.e., \( d = 2 \) or \( d = 3 \). Let us assume that all domains \( \Omega_\ell \) are Lipschitz polyhedra in \( \mathbb{R}^3 \) or polygons in \( \mathbb{R}^2 \). We can thus separate \( \Gamma \) into a finite collection of relatively open flat surfaces (resp. segments) \( \Gamma_1, \ldots, \Gamma_M \) so that for all \( \ell \), there exists an index set \( I(\ell) \subseteq \{1, \ldots, M\} \) such that

\[
\partial \Omega_\ell = \bigcup \{ \Gamma_i : i \in I(\ell) \}.
\]

We consider a conforming triangulation of \( \Gamma \) that respects the subdivision of \( \Gamma \) into the subsets \( \Gamma_i \). For instance, we can start with a regular à la Ciarlet partition of the interior of \( \Omega_1 \cup \ldots \cup \Omega_M \) into open tetrahedra such that no tetrahedral element intersects \( \Gamma \). In particular, this means that \( \{ T \in \mathcal{T}_h : T \subseteq \Omega_\ell \} \) provides a partition of \( \Omega_\ell \) for \( \ell \geq 1 \). Let then \( \Gamma_h \) be the triangulation of \( \Gamma \) induced by \( \mathcal{T}_h \). We now consider the following finite dimensional spaces of functions defined on the skeleton:

\[
\mathcal{P}_h := \{ \phi_h : \Gamma \to \mathbb{R} : \phi_h|_e \in \mathcal{P}_\rho(e) \quad \forall e \in \Gamma_h \},
\]

\[
\mathcal{Q}_h := \{ \psi_h \in \mathcal{C}(\Gamma) : \psi_h|_e \in \mathcal{P}_{\rho+1}(e) \quad \forall e \in \Gamma_h \},
\]

where \( \mathcal{P}_\rho(e) \) is the space of polynomials of degree up to \( \rho \) defined on (tangential coordinates of) \( e \). We can easily define

\[
\mathcal{Y}_h := \{ (\psi_h|_{\partial \Omega_\ell})_{L=0}^L : \psi_h \in \mathcal{Q}_h \} \subseteq \mathcal{Y},
\]

which is isomorphic to \( \mathcal{Q}_h \). To define \( \mathcal{X}_h \), we introduce sign functions handling orientation. For \( \ell \geq 0, s_\ell : \Gamma \to \{-1,0,1\} \) is constant on each \( \Gamma_i \), \( s_\ell \equiv 0 \) outside \( \partial \Omega_\ell \), and \( |s_\ell| \equiv 1 \) on \( \partial \Omega_\ell \). We then assume that common faces have opposite signs, i.e., for \( \ell \neq j \):

\[
s_\ell + s_j \equiv 0 \quad \text{on } \Gamma_i \text{ for all } i \in I(\ell) \cap I(j).
\]

These sign functions are easy to construct as follows: we assign a normal vector to each \( \Gamma_i \) and then write \( s_\ell|_{\Gamma_i} = 1 \) if the assigned normal is exterior to \( \partial \Omega_\ell \) and \( s_\ell|_{\Gamma_i} = -1 \) otherwise. With these sign functions we can finally define

\[
\mathcal{X}_h := \{ (s_\ell \phi_h|_{\partial \Omega_\ell})_{L=0}^L : \phi_h \in \mathcal{P}_h \},
\]

which is isomorphic to \( \mathcal{P}_h \). The approximation properties of these spaces are inherited from the approximations of \( \mathcal{Q}_h \) and \( \mathcal{P}_h \). The details are in the following proposition:

**Proposition 2.3.** Let all \( \Omega_\ell, \ell = 1, \ldots, L \) be Lipschitz polygons or polyhedrons in 2d or 3d. The spaces \( \mathcal{X}_h \) and \( \mathcal{Y}_h \) defined in (2.6) have the following approximation property for every integer \( 0 \leq r \leq \rho \):

\[
\inf_{\phi_h \in \mathcal{X}_h} \left\| \phi - \phi_h \right\|_{H^{-1/2}} \leq C h^{r+3/2} \sum_{\ell=0}^L \left\| \phi_\ell \right\|_{H^{r+1}_{\text{pw}}(\partial \Omega_\ell)}, \tag{2.7a}
\]

\[
\inf_{\psi_h \in \mathcal{Y}_h} \left\| \psi - \psi_h \right\|_{H^{1/2}} \leq C h^{r+3/2} \sum_{\ell=0}^L \left\| \psi_\ell \right\|_{H^{r+2}_{\text{pw}}(\partial \Omega_\ell)}. \tag{2.7b}
\]
for all $\phi = (\phi_\ell)_{\ell=0}^L \in \mathcal{X}$ with $\phi_\ell \in H^{r+1}_{pw}(\partial \Omega_\ell)$ and all $\psi = (\psi_\ell)_{\ell=0}^L \in \mathcal{Y}$ with $\psi_\ell \in H^{r+2}_{pw}(\partial \Omega_\ell)$ and with the additional restriction that the lifting $u \in H^1(\mathbb{R}^d)$ from (2.3b) is a continuous function on $\Gamma$.

**Proof.** We start with the estimate for $\phi$. For each $i \in \{0, \ldots, M\}$, we pick a subdomain $\Omega_\ell$, such that $i \in I(\ell)$, and set $\phi_\ell |_{\Gamma_i} := s_{\ell,i} \Pi_i \phi_\ell |_{\Gamma_i}$, where $\Pi_i \phi_\ell$ is the orthogonal projection with respect to the $L^2$-product on $\Gamma_i$ onto the set of discontinuous piecewise polynomials. Since $\mathcal{P}_h$ is only required to be $L^2$-conforming, this defines a function in $\mathcal{X}_h$ via $\phi^h := (\phi^h_\ell) := (s_{\ell,i} \phi^h |_{\partial \Omega_\ell})_{\ell=0}^L$. It follows from standard estimates (see, e.g., [SS11, Thm. 4.3.20]),

$$\left\| \phi_\ell - \phi^h_\ell \right\|_{L^2(\Gamma_i)} \lesssim h^{r+1} \|\phi_\ell\|_{H^{r+1}(\Gamma_i)}.$$ 

Since the functions $\phi \in \mathcal{X}$ agree on shared interfaces up to the changed sign, i.e. $\phi_{\ell,i} = s_{\ell,i} s_{\ell,i} \phi_\ell$, it is easy to that for arbitrary $\ell = 0, \ldots, L$

$$\left\| \phi_\ell - \phi^h_\ell \right\|_{L^2(\partial \Omega_\ell)}^2 \lesssim \sum_{i=1}^M \left\| \partial_{\ell,i} \phi_\ell - \Pi_i \phi_\ell \right\|_{L^2(\Gamma_i)}^2 \lesssim h^{r+1} \sum_{i=1}^M \|\phi_\ell\|_{H^{r+1}(\Gamma_i)}^2.$$ 

To get an estimate in the $H^{-1/2}$-norm, we can use a standard duality argument, (see [SS11, Thm. 4.3.20]), using the fact that $\phi_\ell - \phi^h_\ell$ is orthogonal to the piecewise polynomials on each face gaining an extra factor $\sqrt{h}$ in the process.

For estimating $\psi$, we note that our assumptions on the lifting $u$ implies that the functions $\psi_\ell$ are continuous on $\partial \Omega_\ell$, most notably at the boundary of the facets. Therefore, we may employ a nodal interpolation operator $I_\ell$. It is well known that if $d \leq 3$

$$\|\psi_\ell - I_\ell \psi_\ell\|_{H^{1/2}(\partial \Omega_\ell)} \lesssim h^{r+3/2} \|\psi_\ell\|_{H^{r+2}_{pw}(\partial \Omega_\ell)},$$

see [SS11, Thm. 4.3.22]. Since the functions $\psi_\ell, \psi_k$ are assumed to be traces of a continuous function $u$, they must coincide on $\partial \Omega_\ell \cap \partial \Omega_k$. This means that the interpolated functions $I_\ell \psi_\ell$ also coincide on $\partial \Omega_\ell \cap \partial \Omega_k$ or $(I_\ell \psi_\ell)_{\ell=0}^L \in \mathcal{X}_h$. \hfill $\square$

### 2.4 Towards an analyzable form

For the sake of analysis (also of the forthcoming time discretization), we find it advantageous to introduce some further notation. The norms of $L^2(\Omega)$ and $L^2(\Omega)^d$ will be equally denoted $\| \cdot \|_\Omega$. We now consider:

(a) The product spaces $\mathcal{L} := L^2(\mathbb{R}^d)^{L+1}$ and $\mathcal{L}^2 := (L^2(\mathbb{R}^d)^d)^{L+1}$.

(b) The natural componentwise differential operators $\nabla : \mathcal{H} \to \mathcal{L}^2$ and $\nabla : \mathcal{H}^{\text{div}} \to \mathcal{L}^2$.

(c) The diagonal scaling operators $T_{c^2} : \mathcal{L} \to \mathcal{L}$ and $T_{\kappa} : \mathcal{L} \to \mathcal{L}$ given by

$$T_{c^2}(u_\ell)_{\ell=0}^L = (c^2 \ell u_\ell)_{\ell=0}^L, \quad T_{\kappa}(w_\ell)_{\ell=0}^L = (\kappa \ell w_\ell)_{\ell=0}^L.$$
(d) A second layer of product spaces given by $\mathbb{H} := L^2 \times L^2$, $\mathbb{V} := \mathcal{H}_\Gamma^{1/2} \times \mathcal{H}_\Gamma^{-1/2}$, and $\mathcal{V} := \mathcal{H} \times \mathcal{H}^{\text{div}}$, where $\mathcal{V}$ and $\mathbb{B}$ are endowed with the product norm, while in $\mathbb{H}$ we consider the weighted norm

$$
\|(u, w)\|_H^2 = \|(u_{\ell})_{\ell=0}^L, (w_{\ell})_{\ell=0}^L\|_H^2 := \sum_{\ell=0}^L c_{\ell}^{-2} \|u_{\ell}\|_{\mathcal{V}}^2 + \sum_{\ell=0}^L \kappa_{\ell}^{-1} \|w_{\ell}\|_{\mathcal{V}}^2,
$$

with the associated inner product given by

$$
\left\langle (u, w), (v, p) \right\rangle_H = \left\langle \left((u_{\ell})_{\ell=0}^L, (w_{\ell})_{\ell=0}^L\right), \left((v_{\ell})_{\ell=0}^L, (p_{\ell})_{\ell=0}^L\right) \right\rangle_H
= \sum_{\ell=0}^L c_{\ell}^{-2} (u_{\ell}, v_{\ell})_{L^2(\mathbb{R}^d)} + \sum_{\ell=0}^L \kappa_{\ell}^{-1} (w_{\ell}, p_{\ell})_{\mathcal{V}}.
$$

(e) The operator $A_\star : \mathcal{V} \to \mathbb{H}$ (see the right-hand side of (2.5a)) given by

$$
A_\star(u, w) := (T_c \nabla \cdot w, T_c \nabla u).
$$

(f) The space $\mathcal{M} := (\mathcal{Y}_h^\nu)' \times (\mathcal{X}_h^\nu)' \times \mathcal{X}_h^\nu \times \mathcal{Y}_h^\nu$, endowed with the product dual norm, where in $\mathcal{X}_h$ and $\mathcal{Y}_h^\nu$ we use the $\mathcal{H}_\Gamma^{-1/2}$ norm and in $\mathcal{Y}_h$ and $\mathcal{X}_h^\nu$ we use the $\mathcal{H}_\Gamma^{1/2}$ norm.

(g) The boundary operator $B_h : \mathcal{V} \to \mathcal{M}$ given by

$$
B_h(u, w) := (\|\gamma u\|_{\mathcal{Y}_h^\nu}, \|\gamma \nu \cdot w\|_{\mathcal{X}_h^\nu}, \gamma^\text{ext} u|_{\mathcal{X}_h}, \gamma^\text{ext} \nu|_{\mathcal{Y}_h}).
$$

The operator $N_h : \mathcal{B} \to \mathcal{M}$ given by $N_h \xi = N_h(\xi^0, \xi^1) := -(\xi^0|_{\mathcal{Y}_h^\nu}, \xi^1|_{\mathcal{X}_h^\nu}, 0, 0)$.

In the definitions of $B_h$ and $N_h$ we use the same notational convention as in [HQSVS17] that we explain with the first component of $B_h$: since $[\gamma u] \in \mathcal{H}_\Gamma^{1/2} = (\mathcal{H}_\Gamma^{-1/2})'$ and $\mathcal{Y}_h^\nu \subseteq H_\Gamma^{-1/2}$, we can consider $[\gamma u]|_{\mathcal{Y}_h^\nu} \in (\mathcal{Y}_h^\nu)'$ as the functional $\mathcal{Y}_h^\nu \ni \xi \mapsto \langle \xi, [\gamma u] \rangle_{\mathcal{Y}_h^\nu}$. Note that

$$
\|N_h \xi(t)\|_M \leq \|\xi(t)\|_B
$$

and that the operator norm of $B_h$ can be bounded independently of the choice of $\mathcal{X}_h$ and $\mathcal{Y}_h$. We can then write problem (2.5) in the following condensed form. We look for $(u^h, w^h) : [0, \infty) \to \mathcal{V}$ satisfying

$$
(\ddot{u}^h(t), \ddot{w}^h(t)) = A_\star(u^h(t), w^h(t)) \quad \forall t \geq 0, \tag{2.9a}
$$

$$
B_h(u^h(t), w^h(t)) = N_h \xi(t) \quad \forall t > 0, \tag{2.9b}
$$

$$
(u^h(0), w^h(0)) = 0. \tag{2.9c}
$$

Occasionally, we will write $A := A_\star|_{\ker(B_h)}$ for the operator endowed with homogeneous boundary conditions, i.e., with $\text{dom}(A) = \ker(B_h) \subseteq \mathcal{V}$.
2.5 Analysis

The next three lemmas will verify the hypotheses of the general framework of [BSVS18, Appendix A], which had streamlined the hypotheses of [HQSVS17, Sect. 3].

**Lemma 2.4.** The following equality holds:

\[
(A_*(u, w), (u, w))_\mathbb{H} = 0 \quad \forall (u, w) \in \ker B_h.
\]

**Proof.** A simple computation, using integration by parts on each subdomain, shows that

\[
(A_*(u, w), (u, w))_\mathbb{H} = \sum_{\ell=0}^L (\gamma_{\nu,\ell}^\text{int} w_\ell, \gamma_{\ell}^\text{int} u_\ell)_{\partial\Omega_\ell} - (\gamma_{\nu,\ell}^\text{ext} w_\ell, \gamma_{\ell}^\text{ext} u_\ell)_{\partial\Omega_\ell}
= (\|\gamma_v w\|, \gamma_{\nu}^\text{int} u)_{\Gamma} + (\gamma_{\nu}^\text{ext} w, \|\gamma_u\|)_{\Gamma} \quad \forall (u, w) \in \mathbb{H}.
\]

(2.10)

Note that \((u, w) \in \ker B_h\) if and only if

\[
\|\gamma_u\| \in \mathcal{Y}_h, \quad \|\gamma_v w\| \in \mathcal{X}_h, \quad \gamma_{\nu}^\text{int} u \in \mathcal{X}_h^0, \quad \gamma_{\nu}^\text{ext} w \in \mathcal{Y}_h^0,
\]

given that \((\|\gamma_u\|, \eta)_{\Gamma} = 0 \forall \eta \in \mathcal{X}_h^0\) implies \(\|\gamma_u\| \in \mathcal{X}_h\) (in short \((\mathcal{X}_h^0)^0 = \mathcal{X}_h\); this is a simple consequence of the closedness of \(X_h\) and the Hahn-Banach theorem). Similarly, \((\mathcal{Y}_h^0)^0 = \mathcal{Y}_h\). Since \(\mathcal{Y}_h \subseteq \mathcal{X}_h^0\), the first and third conditions in (2.11) imply \(\gamma_{\nu}^\text{int} u \in \mathcal{X}_h^0\). The result is then a consequence of (2.10).

**Lemma 2.5.** For all \((f, g) \in \mathbb{H}\) and \(\zeta \in \mathcal{M}\), there exists a unique \((u, w) \in \mathcal{V}\) such that

\[
(u, w) = A_*(u, w) + (f, g), \quad B_h(u, w) = \zeta,
\]

and there exists a constant \(C > 0\), depending only on the geometry and the physical parameters (and thus independent of the choice of \(X_h\) and \(\gamma_h\)) such that

\[
\|(u, w)\|_\mathbb{H} \leq C(\|(f, g)\|_\mathbb{H} + \|\zeta\|_\mathcal{M}).
\]

**Proof.** We write \(f = (f_\ell)_{\ell=0}^L\), \(g = (g_\ell)_{\ell=0}^L\), and \(\zeta = (\zeta_1, \zeta_2, \zeta_3, \zeta_4)\). Consider the space

\[
\mathcal{W} := \{v \in \mathcal{H} : \|\gamma_v v\| \in \mathcal{Y}_h, \gamma_{\nu}^\text{ext} v \in \mathcal{X}_h^0\}
\]

\[
\mathcal{Y}_h \subseteq \mathcal{X}_h^0 \subseteq \{v \in \mathcal{H} : \|\gamma_v v\| \in \mathcal{Y}_h, \gamma_{\nu}^\text{int} v \in \mathcal{X}_h^0\} = \{v \in \mathcal{H} : (v, 0) \in \ker B_h\},
\]

and

\[
a(u, v) := \sum_{\ell=0}^L c_\ell^{-2}(u_\ell, v_\ell)_{\mathbb{R}^d} + \sum_{\ell=0}^L \kappa_\ell \langle \nabla u_\ell, \nabla v_\ell \rangle_{\mathbb{R}^d \setminus \partial\Omega_\ell},
\]

\[
b(v) := \sum_{\ell=0}^L c_\ell^{-2}(f_\ell, v_\ell)_{\mathbb{R}^d} - \sum_{\ell=0}^L (g_\ell, \nabla v_\ell)_{\mathbb{R}^d \setminus \partial\Omega_\ell} + \langle \zeta_2, \gamma_{\nu}^\text{int} v \rangle_{(\mathcal{X}_h^0)^0 \times \mathcal{X}_h^0} + \langle \zeta_4, \|\gamma_u\| \rangle_{\mathcal{Y}_h^0 \times \mathcal{Y}_h^0}.
\]
On the closed subspace $W \subset H$ the bilinear form $a$ is bounded and coercive with constants depending only on the physical coefficients. The linear functional $b$ is bounded and 

$$\|b\|_{W^*} \leq C(\|f\|_\mathbb{H} + \|\zeta\|_M).$$

We now look for $u \in H$ satisfying

$$J_{\gamma} u | Y^h = \zeta_1, \quad \gamma^{\text{ext}} u | \mathcal{X}^h = \zeta_3, \quad (2.12a)$$

$$a(u, v) = b(v) \quad \forall v \in W. \quad (2.12b)$$

To that end, we observe that the map $H \ni u \mapsto (-J_{\gamma} u, \gamma^{\text{ext}} u) \in H^{-1/2} \times H^{-1/2}_{\Gamma}$ admits a bounded right-inverse and that the restriction map $H^{-1/2} \times H^{-1/2}_{\Gamma} = (H^{-1/2}_{\Gamma})' \times (H^{-1/2}_{\Gamma})' \to (Y^h)' \times \mathcal{X}^h$ admits a norm preserving right-inverse by the Hahn-Banach theorem. Hence, the linear map that imposes the essential transmission conditions in (2.12a) admits a bounded right-inverse with bound independent of the choice of $\mathcal{X}^h$ and $\mathcal{Y}^h$. Existence of the solution $u$ of (2.12) is therefore ensured by first lifting the essential transmission conditions to get a function $\tilde{u}$ and then solving (2.12b) with homogeneous transmission conditions and a modified right-hand side to obtain a function $u_0 \in W$. (Recall that on this space, the bilinear form $a$ is coercive.) Setting $u = u_0 + \tilde{u}$, we note that the transmission conditions (2.12a) still hold, since by the definition of polar sets $[\gamma u_0] \in \mathcal{Y}^h$ implies $[\gamma u_0]|_{Y^h} = 0$ and $\gamma^{\text{ext}} u_0 \in \mathcal{X}^h$ gives $\gamma^{\text{ext}} u_0|_{X^h} = 0$.

With a solution $u$ to (2.12) in hand, we define $w := T_{\kappa} \nabla \cdot u + g$. It is simple to prove that $T_{\kappa} \nabla \cdot w + f = u$ (therefore $u \in H^{\text{div}}$), where all the operators are applied in a component-wise way and separately on $\Omega_\ell$ and $\mathbb{R}^d \setminus \Omega_\ell$. Hence, $(u, w) = A_\ast(u, w) + (f, g)$. It is also easy to check that

$$\langle [\gamma v], \gamma^{\text{int}} v \rangle_{\Gamma} + \langle \gamma^{\text{ext}} v, [\gamma v] \rangle_{\Gamma} = \langle \zeta_2, \gamma^{\text{int}} v \rangle_{(X^h)' \times X^h} + \langle \zeta_4, [\gamma v] \rangle_{Y^h \times \mathcal{Y}^h} \forall v \in W. \quad (2.13)$$

(2.13) implies $[\gamma v]|_{X^h} = \zeta_2$ and $\gamma^{\text{ext}} v|_{Y^h} = \zeta_4$ in view of the surjectivity of the map

$$\mathcal{W} \ni v \mapsto (\gamma^{\text{int}} v, [\gamma v]) \in X^h \times \mathcal{Y}^h.$$

Together with (2.12a), we see that $B_h(u, w) = \zeta$. The norm bound follows by the construction.

**Lemma 2.6.** The sign flipping operator $\Phi(u, w) = (u, -w)$ is an isometric involution in $\mathbb{H}$ that preserves $\ker B$ and satisfies $\Phi A_\ast = -A_\ast \Phi$.

**Proof.** Straightforward.
Following the arguments in [BSVS18, Appendix A], Lemmas 2.4—2.6 prove that the unbounded operator $A_{\ker B}$ is the infinitesimal generator of a group of isometries in $H$.

**Theorem 2.7.** If $\xi \in C^2([0, \infty); B)$ satisfies $\xi(0) = \dot{\xi}(0) = 0$, then the unique solution of (2.9) satisfies

$$\| (u^h(t), w^h(t)) \|_V \leq C t \max_{0 \leq \tau \leq t} \| \xi(\tau) \|_B + \max_{0 \leq \tau \leq t} \| \dot{\xi}(\tau) \|_B.$$

(2.14)

Moreover, for $\ell \in \mathbb{N}$, if in addition $\xi \in C^{\ell+2}([0, \infty); B)$ and $\xi^{(j)}(0) = 0$ for $j \leq \ell + 1$, we can also estimate

$$\left\| \frac{d^\ell}{dt^\ell} (u^h(t), w^h(t)) \right\|_V \leq C t \sum_{j=\ell}^{\ell+2} \left( \max_{0 \leq \tau \leq t} \| \xi^{(j)}(\tau) \|_B \right).$$

(2.15)

**Proof.** Let $\xi \in C^2([0, \infty); M)$ satisfy $\xi(0) = \dot{\xi}(0) = 0$. Using [BSVS18] (a slight simplification of [HQSVS17]), we can prove that equation (2.9) with boundary condition $B_h(u^h, w^h) = \zeta := N_h \xi$ has a unique classical solution satisfying

$$\| (u^h(t), w^h(t)) \|_M \leq C t \max_{0 \leq \tau \leq t} ( \| \zeta(\tau) \|_M + \| \dot{\zeta}(\tau) \|_M ),$$

(2.16a)

$$\| (\dot{u}^h(t), \dot{w}^h(t)) \|_M \leq C t \max_{0 \leq \tau \leq t} ( \| \zeta(\tau) \|_M + \| \ddot{\zeta}(\tau) \|_M + \| \dot{\zeta}(\tau) \|_M ).$$

(2.16b)

To obtain (2.14) from (2.16), we use (2.8) and (2.9a) and the fact that $\|(u, w)\|_V \sim \| A_s(u, w) \|_M + \|(u, w)\|_H$. The estimate (2.15) follows from a simple shifting argument, i.e., by differentiating the equation. □

### 3 A system of semidiscrete TDBIE

In this section we relate (2.5) with a system of semidiscrete-in-space time-domain boundary integral equations (TDBIE). Some concepts of TDBIE are needed for the sequel. Full details, in the same language, but with a slightly different notation (we use here Lubich’s operational notation) can be found in [Say16].

The retarded potentials for the acoustic wave equation can be introduced through their Laplace transforms and all associated boundary integral operators will be derived using the standard rules of the Calderón calculus [Say16, Chap. 1]. For $s \in \mathbb{C}_+ := \{ z \in \mathbb{C} : \Re(z) > 0 \}$, we denote the fundamental solution for the differential operator $\Delta - s^2$ by

$$\Phi(z; s) := \begin{cases} \frac{i}{4} H_0^{(1)}(is \ | z |), & \text{for } d = 2, \\ e^{-s|z|}, & \text{for } d = 3, \end{cases}$$
where \( H_0^{(1)} \) denotes the Hankel function of the first kind and order zero. We then define the single and double layer potentials for the Laplace resolvent equation

\[
(S_\ell(s) \phi)(x) := \int_{\partial \Omega_\ell} \Phi(x - y; s) \phi(y) \, d\sigma(y),
\]

\[
(D_\ell(s) \psi)(x) := \int_{\partial \Omega_\ell} \partial_\nu(y) \Phi(x - y; s) \psi(y) \, d\sigma(y),
\]

where \( d\sigma \) is the arc/area element on \( \partial \Omega_\ell \). We will use the symbol for normal derivatives \( \partial_\nu := \gamma_\nu \nabla \) in expressions for interior/exterior traces, jumps, and averages.

1. On each boundary \( \partial \Omega_\ell \), we define the single and double layer retarded potentials

\[
S_\ell(\partial_t) \phi := \mathcal{L}^{-1}\{S(\cdot/m_\ell) \mathcal{L}\{\phi\}\}, \quad \text{and} \quad D_\ell(\partial_t) \psi := \mathcal{L}^{-1}\{D(\cdot/m_\ell) \mathcal{L}\{\psi\}\},
\]

where \( m_\ell := c_\ell \sqrt{\kappa_\ell} \) and \( \mathcal{L} \) is the distributional Laplace transform.

2. The subdomain potentials are collected in diagonal operators

\[
S(\partial_t) \phi = S(\partial_t)(\phi)_t^{L=0} := (S_\ell(\partial_t) \phi_t)_t^{L=0}, \quad \text{and} \quad D(\partial_t) \psi = D(\partial_t)(\psi)_t^{L=0} := (D_\ell(\partial_t) \psi_t)_t^{L=0},
\]

and we also introduce

\[
G(\partial_t) := \begin{bmatrix} -D(\partial_t) & S(\partial_t) \end{bmatrix},
\]

which satisfies

\[
\begin{bmatrix} [\gamma] \\ [\partial_\nu] \end{bmatrix} G(\partial_t) = I. \tag{3.1}
\]

3. The matrix with the time domain boundary integral operators (from all \( L+1 \) boundaries and using different wave speeds) is defined by

\[
C(\partial_t) := \begin{bmatrix} \{[\gamma \cdot]\} \\ \{[\partial_\nu \cdot]\} \end{bmatrix} G(\partial_t) = \begin{bmatrix} -K(\partial_t) & V(\partial_t) \\ W(\partial_t) & K^*(\partial_t) \end{bmatrix} \tag{3.2}
\]

(The latter matrix of operators is given for ease of comparison with the literature.) Note that by (3.1) and (3.2), we have

\[
\begin{bmatrix} \gamma_{\text{ext}} \\ \partial_\nu_{\text{ext}} \end{bmatrix} G(\partial_t) = C(\partial_t) - \frac{1}{2}I. \tag{3.3}
\]

4. We introduce the diagonal scaling operator \( Q_\kappa(\psi, \phi)^T := (\psi, (\kappa_t \phi_t)_{t=0}^L)^T \), and the partial anti-differentiation operator \( J(\partial_t)(\xi^0, \xi^1)^T := (\partial_t^{-1} \xi^0, \xi^1) \).
Kirchhoff’s formula (see [Say16, Proposition 3.5.1]) shows that if

\[ \mathbf{u} = T_e \nabla \cdot \mathbf{w}, \quad \mathbf{w} = T_\kappa \nabla \mathbf{u}, \]

(with some very mild distributional regularity conditions and with time-differentiation understood in the sense of vector-valued distributions), then

\[ \mathbf{u} = S(\partial_t)\mathbf{\gamma}_u T_\kappa^{-1} \mathbf{w} - D(\partial_t)\mathbf{\gamma}_u = G(\partial_t) Q_\kappa^{-1}(\mathbf{\gamma}_u, \mathbf{\gamma}_w)^\top. \] (3.4)

A precise statement of a theorem relating a system of semidiscrete TDBIE with a distributional version of (2.5) would use the language of Laplace transformable causal distributions that we will avoid.

To make notation more compact and compatible with the definition of \( G(\partial_t) \), we will collect the \( B \)-part of what we will discretize in time, while we will work with \( \dot{\mathbf{J}} \), then \( \mathbf{J} \) will appear in the somewhat peculiar form \( \mathbf{J}(\partial_t) \tilde{\xi} = (\xi^0, \xi^1) \). The operator \( \mathbf{J}(\partial_t) \) will be part of what we will discretize in time, while we will work with \( \tilde{\xi} \), as data, which means that we will be using \( \gamma^0 \gamma_0^\text{inc} \mathbf{u} \) and \( \gamma^1 \nabla \gamma_0^\text{inc} \mathbf{u} \) as data for the numerical method expressed with TDBIE (see Proposition 2.2), i.e., we either differentiate the incident wave in space or in time. When the incident wave is a plane wave \( \mathbf{u}^\text{inc}(t)(\mathbf{x}) = g(\mathbf{x} \cdot \mathbf{d} - t) \) (for \( \mathbf{d} \in \mathbb{R}^d \) with \( |\mathbf{d}| = 1 \)), we will only need to evaluate \( \dot{g}(\mathbf{x} \cdot \mathbf{d} - t) \) for points \( \mathbf{x} \in \partial \Omega_0 \).

**Theorem 3.1.** If \( (\mathbf{u}^h, \mathbf{w}^h) \) is a \( \mathcal{V} \)-valued causal distribution satisfying

\[ (\dot{\mathbf{u}}^h, \mathbf{w}^h) = \mathbf{A}_x(\mathbf{u}^h, \mathbf{w}^h), \quad \mathbf{B}_h(\mathbf{u}^h, \mathbf{w}^h) = \mathbf{N}_h \tilde{\xi}, \] (3.5)

then \( \mathbf{\lambda}^h := (\mathbf{\gamma}_u^h + \xi^0, \mathbf{\gamma}_w^h + \xi^1)^\top \) is the unique \( \mathbb{B} \)-valued causal distribution satisfying

\[ \mathbf{\lambda}^h \in \mathcal{Y}_h \times \mathcal{X}_h, \quad (Q_x C(\partial_t) Q_\kappa^{-1} \mathbf{\lambda}_h, \varpi) = (Q_x (C(\partial_t) - \frac{1}{2}I) Q_\kappa^{-1} \mathbf{J}(\partial_t) \tilde{\xi}, \varpi) \quad \forall \varpi \in \mathcal{X}_h \times \mathcal{Y}_h, \] (3.6a)

\[ (Q_x C(\partial_t) Q_\kappa^{-1} \mathbf{\lambda}_h, \varpi) = (Q_x (C(\partial_t) - \frac{1}{2}I) Q_\kappa^{-1} \mathbf{J}(\partial_t) \tilde{\xi}, \varpi) \quad \forall \varpi \in \mathcal{X}_h \times \mathcal{Y}_h, \] (3.6b)

where the angled bracket is the \( \mathbb{B} \times \mathbb{B}' \) duality product. Reciprocally, if \( \mathbf{\lambda}^h \) is the solution of (3.6) and we let

\[ \mathbf{u}^h := G(\partial_t) Q_\kappa^{-1} (\mathbf{\lambda}_h - \mathbf{J}(\partial_t) \tilde{\xi}), \quad \mathbf{w}^h = T_\kappa \nabla \partial_t^{-1} \mathbf{u}^h, \] (3.7)

then \( (\mathbf{u}^h, \mathbf{w}^h) \) satisfies (3.5).

**Proof.** First of all the boundary conditions in (3.5) are equivalent to

\[ \mathbf{\gamma}_u^h \mathbf{u}^h + \xi^0 \in \mathcal{Y}_h, \quad \mathbf{\gamma}_w^h \mathbf{w}^h + \xi^1 \in \mathcal{X}_h, \] (3.8a)

\[ \mathbf{\gamma}_u^\text{ext} \mathbf{u}^h \in \mathcal{X}_h^0, \quad \mathbf{\gamma}_w^\text{ext} \mathbf{w}^h \in \mathcal{Y}_h^0. \] (3.8b)

(Compare with (2.5) and note that we have differentiated the conditions related to \( \mathbf{w}^h \) for later convenience.) Given a solution to (3.5), we can use (3.4) to write the pair
\( (u^h, w^h) \) in the form (3.7). The condition (3.8a) is equivalent to \( \lambda^h \in Y_h \times X_h \), while (3.8b) is equivalent (using (3.3)) to
\[
Q_\kappa(C(\partial_t) - \frac{1}{2}I)Q_\kappa^{-1}(\lambda^h - J(\partial_t)\xi) \in X^0_h \times Y^0_h. \tag{3.9}
\]
However, since \( Y_h \times X_h \subseteq X^0_h \times Y^0_h \), (3.6a) and (3.9) are equivalent to (3.6a) and
\[
Q_\kappa(C(\partial_t)Q_\kappa^{-1}\lambda^h - Q_\kappa(C(\partial_t) - \frac{1}{2}I)Q_\kappa^{-1}J(\partial_t)\xi) \in X^0_h \times Y^0_h. \tag{3.10}
\]
But (3.10) is just a short hand version of (3.6b). The proof of the reciprocal statement is very similar. \( \square \)

The estimates of Theorem 2.7 hold for the solution of (3.6) if we prove (which can be easily done using the techniques of [HQSVS17, Sect. 3]) that the strong solution of (2.5), extended by zero to negative times, is the distributional solution of (3.8).

**Theorem 3.2.** Assume that \( \xi \in C^0([0, \infty); \mathbb{B}) \) with \( \xi^{(\ell)}(0) = 0 \) for \( \ell = 0, \ldots, 5 \). Let \( \lambda = (\psi, \phi)^\top \) be the solution of
\[
\lambda \in Y \times X, \tag{3.11a}
\]
\[
\langle Q_\kappa C(\partial_t)Q_\kappa^{-1}\lambda, \varpi \rangle = \langle Q_\kappa(C(\partial_t) - \frac{1}{2}I)Q_\kappa^{-1}J(\partial_t)\xi, \varpi \rangle \quad \forall \varpi \in X \times Y, \tag{3.11b}
\]
and let \( \lambda^h = (\psi^h, \phi^h)^\top \) be the solution of (3.6). Consider the associated potentials
\[
u = G(\partial_t)Q_\kappa^{-1}(\lambda - J(\partial_t)\xi), \quad u^h = G(\partial_t)Q_\kappa^{-1}(\lambda^h - J(\partial_t)\xi).
\]
Then:
\[
\|u(t) - u^h(t)\|_Y \leq Ct \max_{0 \leq \tau \leq t} \|((\psi^{(j + 1)}, \phi^{(j)})(\tau) - \Pi(\psi^{(j + 1)}, \phi^{(j)})(\tau))\|_\mathbb{B},
\]
\[
\|\psi(t) - \psi^h(t)\|_{H^{1/2}} \leq Ct \max_{0 \leq \tau \leq t} \|((\psi^{(j + 1)}, \phi^{(j)})(\tau) - \Pi(\psi^{(j + 1)}, \phi^{(j)})(\tau))\|_\mathbb{B},
\]
\[
\|\phi(t) - \phi^h(t)\|_{H^{-1/2}} \leq Ct \max_{0 \leq \tau \leq t} \|((\psi^{(j + 1)}, \phi^{(j)})(\tau) - \Pi(\psi^{(j + 1)}, \phi^{(j)})(\tau))\|_\mathbb{B},
\]
where \( \Pi : \mathbb{B} \to Y_h \times X_h \) is the best approximation operator onto \( Y_h \times X_h \).

**Proof.** We consider the difference \( e := (e_1, e_2) := (u, w) - (u^h, w^h) \). This function solves the differential equation \( \dot{e} = A_t e \), and the transmission conditions satisfied by \( u^h \) give the following transmission conditions for \( e \):
\[
\left\| \gamma \nu e_1 \right\| (t) - \left\| \gamma u \right\| (t) - \xi^0(t) \in Y_h, \quad \left\| \gamma \nu' e_2 \right\| (t) - \left\| \gamma v \right\| (t) - \xi^1(t) \in X_h,
\]
where \( \gamma^e_1(t) \in X^0_h, \quad \gamma^e_2(t) \in Y^0_h \).
for all \( t \geq 0 \). Secondly, we notice that these conditions are invariant under subtracting discrete functions, i.e., for \( \chi_h(t) \in Y_h, \mu_h(t) \in X_h \), they are equivalent to the following conditions:

\[
\begin{align*}
[\gamma e_1](t) - \psi(t) + \chi_h(t) & \in Y_h, \\
\gamma e_2](t) - \partial_t^{-1}\phi(t) + \mu_h(t) & \in X_h,
\end{align*}
\]

where we also inserted the definitions of \( \psi \) and \( \lambda \) to shorten notation. This is structurally the same as (2.5). Using the best approximation operator \( \Pi \), setting \( (\chi_h(t), \mu_h(t)) := \Pi \lambda(t) \) and applying the stability estimate of Theorem 2.7 gives the estimate for \( u - u_h \).

The bound for \( \|\psi(t) - \psi^h(t)\|_{H^{1/2}} = \|[\gamma(\psi(t) - \phi^h(t))]\|_{H^{1/2}} \) follows from the trace theorem. Finally, the bound for

\[
\|\phi(t) - \phi^h(t)\|_{H^{1/2}} = \|[\gamma(\phi(t) - \psi^h(t))]\|_{H^{1/2}} \leq C\|\phi(t) - \phi^h(t)\|_{H^{div}}
\]

requires (2.15). The requirements on \( \xi \) are such that the exact traces \( \psi \) and \( \phi \) have the required regularity by Theorem 2.7.

\[\square\]

4 Time discretization - Runge Kutta convolution quadrature

An implicit Runge-Kutta method with \( m \) stages is given by a matrix \( Q \in \mathbb{R}^{m \times m} \) and two vectors \( b, c \in \mathbb{R}^m \). Its stability function is the rational function \( r(z) := 1 + z b^\top (I - zQ)^{-1} 1 \), where \( 1 := (1, \ldots, 1)^\top \). In everything that follows, we will always assume that \( Q \) is invertible, which is a necessary condition to be in the framework of RK-based convolution quadrature methods. Therefore, the limit \( r(\infty) = \lim_{z \to \infty} r(z) = 1 - b^\top Q^{-1} 1 \) exists. We say that the RK method is:

1. (a) A-stable when \( |r(it)| \leq 1 \) for all \( t \in \mathbb{R} \),
2. (b) strictly A-stable when \( |r(it)| < 1 \) for \( t \in \mathbb{R} \) \( \setminus \{0\} \) and \( r(\infty) < 1 \),
3. (c) stiffly accurate, when \( b^\top Q^{-1} = (0, \ldots, 0, 1) \) and therefore \( c_m = 1 \) and \( r(\infty) = 0 \).

We will assume that the stage order of the RK method is \( q \), while its classical order is \( p \geq q \). The methods of the Radau IIa family of RK methods have invertible matrix \( Q \), are strictly A-stable and stiffly accurate. These methods are standard for applications in convolutions quadrature, despite their damping properties, which are not ideal for wave equations. This is in part due to the fact that the standard theory (see, e.g., [BLM11]) makes some assumptions not satisfied by the Gauss methods. We also would like to point out that in higher order methods the dissipation and dispersion is much better controlled than for the low order cousins [BS12, Section 4.3], which is another good reason for utilizing Runge-Kutta methods for wave propagation applications.
4.1 The fully discrete method

In Section 3 we have introduced operators $H(\partial_t)$ (with $H \in \{C, G, J\}$) such that there exists an analytic function $H : \mathbb{C}_+ \to B(\mathcal{Z}_1, \mathcal{Z}_2)$ (here $\mathbb{C}_+ := \{ z \in \mathbb{C} : \Re z > 0 \}$ and $B(\mathcal{Z}_1, \mathcal{Z}_2)$ is the space of bounded linear operators between two Hilbert spaces) such that
\[ \mathcal{L}\{H(\partial_t)\xi\} = H\mathcal{L}\{\xi\}. \]

We can then expand
\[ H \left( \frac{z}{1-z} \right) = \sum_{j=0}^{\infty} z^j H_j, \]

where evaluating $H$ with a matrix as its argument can be done with Riesz-Dunford calculus (see [GVL13, Chap. 11] or [Yos80, Chap. VIII.7]), and the series is a Maclaurin expansion of an analytic function with coefficients $H_j \in B(\mathcal{Z}_m^1; \mathcal{Z}_m^2)$. Note that for $|z| < 1$ the spectrum of $Q - (1-z)^{-1}z b^\top$ is contained in $\mathbb{C}_+$ for every A-stable RK method with invertible $Q$ by [BLM11, Lemma 3].

The discrete convolution defined by the above sequence of operators
\[ Y_n := \sum_{j=0}^{n} H_j \Xi_{n-j}, \quad n \geq 0, \]
transforms sequences in $\mathcal{Z}_1^m$ into sequences in $\mathcal{Z}_2^m$ and will be denoted $Y = H(\partial_k)\Xi$.

Additionally, we can produce a sequence in $\mathcal{Z}_2$ in the postprocessed form
\[ y_0 := 0, \quad y_n := r(\infty)y_{n-1} + b^\top Q^{-1}Y_{n-1}, \quad n \geq 1, \quad (4.1) \]

which in the case of stiffly accurate RK methods just delivers the sequence with the $m$-th components of $\{Y_n\}$, namely $y_n = (0, \ldots, 0, 1)Y_{n-1}$. The postprocessing step described in (4.1) will be denoted $\{y_n\} = \mathbb{P}\{Y_n\}$. The computation of $y = \partial_t^{-1}\Xi$ (the RK-CQ method when $H(s) = s^{-1}$) can be easily seen to be equivalent to the recurrence
\[ y_0 := 0, \quad Y_n = 1y_n + kQ\Xi_n, \quad y_{n+1} = r(\infty)y_n + b^\top Q^{-1}Y_n, \quad n \geq 0, \quad (4.2) \]

which computes the ‘postprocessed’ sequence simultaneously. When $\Xi_n = (\xi(t_n + c_1 k), \ldots, \xi(t_n + c_m k))^\top$, this is just the application of the RK method to
\[ \dot{y}(t) = \xi(t), \quad t \geq 0, \quad y(0) = 0, \]

which we can write as the operator equation $y = \partial_t^{-1}\xi$. In (4.1) and (4.2) we have used the product of scalar matrices by elements of $\mathcal{Z}_2^m$, which has to be understood as taking linear combinations of elements of $\mathcal{Z}_2$ using the coefficients of the matrix. We will also use the following instance of Kronecker products: given $R \in B(\mathcal{Z}_1, \mathcal{Z}_2)$ we denote
\[ \tilde{R} := I_{m \times m} \otimes R := \begin{bmatrix} R \\ \vdots \\ R \end{bmatrix} \in B(\mathcal{Z}_1^m; \mathcal{Z}_2^m). \quad (4.3) \]
The fully discrete numerical method that we propose and analyze is an RK-CQ discretization of (3.6), followed by the RK-CQ discretization of the potentials (3.7). We start by sampling the data

$$\tilde{\Xi}^k := \{\tilde{\xi}(t_n + ck)\}_{n=0}^\infty, \quad t_n := nk.$$  

(4.4a)

Next we compute a sequence

$$\Lambda^{h,k} = \{\Lambda^{h,k}_n\}_{n=0}^\infty, \quad \Lambda^{h,k}_n \in (\mathcal{Y}_h \times \mathcal{X}_h)^m,$$  

(4.4b)

satisfying

$$\langle \tilde{Q}_k C(\partial_k) \tilde{Q}_k^{-1} \Lambda^{h,k}, \varpi \rangle = \langle \tilde{Q}_k (C(\partial_k) - \frac{1}{2}1) \tilde{Q}_k^{-1} J(\partial_k) \tilde{\Xi}^k, \varpi \rangle \quad \forall \varpi \in (\mathcal{X}_h \times \mathcal{Y}_h)^m.$$  

(4.4c)

The expression (4.4c) represents a discrete convolutional system that yields the different time-values of the sequence $\Lambda^{h,k}$ as a recursion. Each time step requires the solution of a square linear system of equations with $m(\dim \mathcal{Y}_h + \dim \mathcal{X}_h)$ unknowns. We finally compute

$$U^{h,k} = G(\partial_k) \tilde{Q}_k^{-1} (\Lambda^{h,k} - J(\partial_k) \tilde{\Xi}^k), \quad W^{h,k} = \tilde{T}_n \tilde{\nabla} \tilde{\partial}_k^{-1} U^{h,k}. $$  

(4.4d)

Corresponding to these stage vectors, we can then define the approximations at the endpoints via

$$\lambda^{h,k} := (\psi^{h,k}, \phi^{h,k}) := P \Lambda^{h,k}, \quad u^{h,k} = P U^{h,k}, \quad w^{h,k} := P W^{h,k}. $$  

(4.4e)

(Here we committed the slight abuse of notation and identified $(\mathcal{X}_h \times \mathcal{Y}_h)^m$ with $(\mathcal{X}^m_h \times \mathcal{Y}^m_h)$.)

Our next effort is to relate (4.4) with a discretization of a certain IBVP related to the pair $x^h := (u^h, w^h)$, in the same way that Theorem 3.1 related the semidiscrete system of TDBIE (3.6), postprocessed with the retarded potential expressions (3.7) to a weak-in-time version of (2.9). In strong form, $x^h := (u^h, w^h) : [0, \infty) \to \mathcal{V}$ satisfies

$$\dot{x}^h(t) = A_x x^h(t), \quad B_h \dot{x}^h(t) = N_h \dot{\xi}(t), \quad x^h(0) = 0,$$  

(4.5)

which is equivalent to (2.9). The boundary condition can equivalently be written $B x^h = \tilde{\partial}_t^{-1} \tilde{N}_x = \tilde{N}_\xi$, but, as we have already mentioned, we will use $\dot{\xi}$ as data. An RK-CQ approximation of (4.5) simply substitutes time derivatives by $\tilde{\partial}_k$:

$$\partial_k x^{h,k} = \tilde{A}_x x^{h,k}, \quad \tilde{B}_h \partial_k x^{h,k} = \tilde{N}_h \tilde{\Xi}^k, \quad x^{h,k} = P x^{h,k}. $$  

(4.6)

This can also be written in RK form

$$x^{h,k}_0 = 0, \quad x^{h,k}_n = x^{h,k}_{n+1} + k Q \tilde{A}_x x^{h,k}_n, \quad \tilde{B}_h x^{h,k}_n = \Theta^{h,k}_n, \quad x^{h,k}_{n+1} = x^{h,k}_n + k b^\top \tilde{A}_x x^{h,k}_n + r(\infty) x^{h,k}_n + b^\top Q^{-1} x^{h,k}_n,$$  

(4.7a)

where $\Theta^k = \{\Theta^k_n\} := \tilde{N}_h \partial_k^{-1} \tilde{\Xi}^k$.  

19
Proposition 4.1. If $\Lambda^{h,k}, U^{h,k}, W^{h,k}$ solve (4.4), then $X^{h,k} := (U^{h,k}, W^{h,k})$ solves (4.6). Reciprocally, if $X^{h,k} = (U^{h,k}, W^{h,k})$ solves (4.6), then the shifted traces $\Lambda^{h,k} := ([\tilde{\gamma} U^{h,k}], [\tilde{\gamma}_\nu W^{h,k}])^\top + \partial_k^{-1} \Sigma^k$ satisfy (4.4b)-(4.4c) and (4.4d) holds.

Proof. Taking the Laplace transforms of the corresponding continuous problems (Theorem 3.1) and Z-transforms of the discrete problems (4.4) and (4.6), we can easily prove the statement. See [MR17] for a detailed analogous computation.

In Section 6 (numerical experiments), we will compare (4.4) with a method that has $J(\partial_t)\xi$ as data, i.e., where $J(\partial_t)$ is not discretized in the time variable. In this method we first sample $\Sigma^k := \{ \xi_0(t_n + ck), \xi_1(t_n + ck) \}_{n=0}^\infty$, (4.8a)

next look for $\Lambda^{h,k} = \{ \Lambda_n^{h,k} \}_{n=0}^\infty$, $\Lambda_n^{h,k} \in (\mathcal{Y}_h \times \mathcal{X}_h)^m$ (4.8b)

satisfying $(\tilde{\Omega}_n C(\partial_k) \tilde{\Omega}_n^{-1} \Lambda^{h,k}, \varpi) = (\tilde{\Omega}_n (C(\partial_k) - \frac{1}{2} I) \tilde{\Omega}_n^{-1} \Sigma^k, \varpi)$ $\forall \varpi \in (\mathcal{Y}_h \times \mathcal{X}_h)^m$ (4.8c)

and finally postprocess by setting $U^{h,k} = \{ U_n^{h,k} \} := G(\partial_k) \tilde{\Omega}_n^{-1} (\Lambda^{h,k} - \Sigma^k)$, $W^{h,k} = \{ W_n^{h,k} \} := \tilde{T}_n \tilde{\nabla} \partial_k^{-1} U^{h,k}$.

4.2 Some regularity theorems

In this section we verify that the semidiscrete solution to (2.9) satisfies the assumptions of the abstract RK-theory in [AMP03, RSM20].

Lemma 4.2. The map $\mathcal{E} : \mathbb{B} \to \mathcal{V}$, given by $\mathcal{E}\zeta := (u, w)$, where

$$(u, w) = A_{\star}(u, w), \quad B_h(u, w) = N_h \zeta,$$ (4.9)

is well defined and bounded independently of the choice of the spaces $\mathcal{X}_h$ and $\mathcal{Y}_h$.

Proof. It is a direct consequence of Lemma 2.5 and (2.8).

We consider the spaces $\mathbb{H}_\mu := [\mathbb{H}, \ker B_h]_{\mu, \infty}$, $\mu \in (0, 1)$, with $\| \cdot \|_{\ker B_h} := \| \cdot \|_\mathbb{H} + \| A_{\star} \cdot \|_\mathbb{H}$, (4.10)

obtained by the real interpolation method for Banach spaces (see [Tar07, Tri95] or [McL00, Appendix B]). We recall that for two Banach spaces $\mathcal{X}_1 \subseteq \mathcal{X}_0$, the norm is given by:

$$\| u \|_{[\mathcal{X}_0, \mathcal{X}_1]_{\mu, \infty}} := \text{ess sup}_{t > 0} \left( t^{-\mu} \inf_{v \in \mathcal{X}_1} \left[ \| u - v \|_{\mathcal{X}_0} + t \| v \|_{\mathcal{X}_1} \right] \right).$$ (4.11)

Lemma 4.3. For $\mu \leq 1/2$, the map $\mathcal{E}$ of (4.9) is bounded from $\mathcal{H}_1^{1/2} \times \mathcal{H}_1^{-1/2 + \mu}$ to $\mathbb{H}_\mu$. 20
Proof. For \( \mu = 0 \), the statement follows from Lemma 4.2. We focus on \( \mu = 1/2 \). Given \( \zeta_0 \in \mathcal{H}^{1/2} \), we take \( u_0 \in \mathcal{H} \) satisfying
\[
-\Delta u_0 + u_0 = 0, \quad \gamma^\text{int} u_0 = \zeta_0, \quad \gamma^\text{ext} u_0 = 0.
\]
This is a collection of \( L + 1 \) decoupled interior-exterior Dirichlet problems in \( \mathbb{R}^d \setminus \partial \Omega_\ell \) with vanishing exterior components in all cases. We claim that each component of \( u_0 = (u_{0,\ell})_{\ell=0}^{L} \) satisfies
\[
u_{0,\ell} \in \left[ L^2(\mathbb{R}^d), H^1_0(\mathbb{R}^d \setminus \partial \Omega_\ell) \right]_{\frac{1}{2},\infty}.
\]
This follows from the observation \( u_{0,\ell} \in H^1(\mathbb{R}^d \setminus \partial \Omega_\ell) \), the embeddings \( H^1(\omega) \subset B^{1/2}_{2,1}(\omega) \subset [L^2(\omega), H^1_0(\omega)]_{1/2,\infty} \) (for \( \omega \in \{ \Omega_\ell, \mathbb{R}^d \setminus \Omega_\ell \} \) asserted in [RSM20, Thm. A.1]. Given \( \zeta_1 = (\zeta_{1,\ell})_{\ell=0}^{L} \in \prod_\ell L^2(\partial \Omega_\ell) \), we use [RSM20, Thm. A.4] to construct on each subdomain a function \( w_{0,\ell} \in H(\text{div}, \Omega_\ell) \) with
\[
\gamma^\text{int} w_{0,\ell} = \zeta_{1,\ell}, \quad \text{and} \quad \| w_{0,\ell} \|_{[L^2(\Omega_\ell), H^1_0(\text{div}, \Omega_\ell)]_{\frac{1}{2},\infty}} \lesssim \| \zeta_{1,\ell} \|_{L^2(\Omega_\ell)}.
\]
Here, \( H^1_0(\text{div}, \Omega_\ell) \) denotes the functions in \( H(\text{div}, \Omega_\ell) \) with vanishing interior normal trace. Similarly, we write \( H_0(\text{div}, \mathbb{R}^d \setminus \partial \Omega_\ell) \) for functions with vanishing interior and exterior normal traces.

Extending these functions \( w_{0,\ell} \) by zero outside \( \Omega_\ell \) and collecting them in \( w_0 := (w_{0,\ell})_{\ell=0}^{L} \), we get \( w_0 \in \mathcal{H}^{\text{div}} \) satisfying
\[
\gamma^\text{int} w_0 = \zeta_1, \quad \gamma^\text{ext} w_0 = 0.
\]
Since true zero boundary conditions are stronger than those imposed by \( \ker(\mathbf{B}_h) \) it is easy to see that
\[
\prod_{\ell=0}^{L} H^1_0(\mathbb{R}^d \setminus \Omega_\ell) \times \prod_{\ell=0}^{L} H_0(\text{div}, \mathbb{R}^d \setminus \Omega_\ell) \subset \ker(\mathbf{B}_h) = \text{dom}(\mathbf{A}).
\]
Since interpolation of product spaces corresponds to the product of interpolation spaces (see [Tri95, Sect. 1.18.1]), we get that
\[
(u_0, w_0) \in \prod_{\ell=0}^{L} \left[ L^2(\mathbb{R}^d), H^1_0(\mathbb{R}^d \setminus \partial \Omega_\ell) \right]_{\frac{1}{2},\infty} \times \prod_{\ell=0}^{L} \left[ L^2(\mathbb{R}^d \setminus \partial \Omega_\ell), H_0(\text{div}, \mathbb{R}^d \setminus \partial \Omega_\ell) \right]_{\frac{1}{2},\infty}
\]
\[
= \left[ L^2, \prod_{\ell=0}^{L} H^1_0(\mathbb{R}^d \setminus \Omega_\ell) \right]_{\frac{1}{2},\infty} \times \left[ L^2, \prod_{\ell=0}^{L} H_0(\text{div}, \mathbb{R}^d \setminus \Omega_\ell) \right]_{\frac{1}{2},\infty} \subset H^{1/2}. \]
Since all these inclusions come with norm estimates, we thus have a bounded operator
\[
\mathbb{B} : \zeta \mapsto (u_0, w_0) \in \mathcal{V}
\]
(this is not the lifting \( \mathcal{E} \)) such that

\[
\mathcal{H}^{1/2}_1 \times \mathcal{H}^0_1 \ni \zeta \mapsto (u_0, w_0) \in \mathbb{H}_{1/2}
\]

is also bounded. Therefore, for \((u, w) := \mathcal{E} \zeta\), we have

\[
(u - u_0, w - w_0) \in \ker B_h \subseteq \mathbb{H}_{1/2}.
\]

Since for elements of \(\ker B_h\) the \(\mathbb{H}_{1/2}\) norm can be estimated by the \(V\) norm, (cf. (4.10)) in which \(\mathcal{E}\) is bounded, this concludes the proof for \(\mu \in \{0, 1/2\}\). An interpolation argument and the reiteration theorem [Tar07, Theorem 26.3], extends this bound to \(\mu \in [0, 1/2]\).

To shorten some expressions, we introduce notation for the norm on the right-hand side of (4.13). For \(m \in \mathbb{N}\) and \(\psi \in C^m([0, T], H^{1/2}(\partial \Omega_0))\), \(\phi \in C^{m-1}([0, T], H^{-1/2+\mu}(\partial \Omega_0))\), \(\mu \in [0, 1/2]\), we write

\[
\|\psi, \phi\|_{m, T, \mu} := \sum_{j=0}^{m} \sup_{0 \leq t \leq T} \left( \|\psi^{(j)}(t)\|_{H^{1/2}(\partial \Omega_0)} + \|\phi^{(j-1)}(t)\|_{H^{-1/2+\mu}(\partial \Omega_0)} \right). \tag{4.12}
\]

Lemma 4.3 then directly gives the following corollary for the semidiscrete solution:

**Corollary 4.4.** For \(\mu \in [0, 1/2]\) and \(m \in \mathbb{N}_0\), let \(\gamma u^{inc} \in C^{m+2}([0, T], H^{1/2}(\partial \Omega_0))\) and \(\partial_\nu u^{inc} \in C^{m+1}([0, T], H^{-1/2+\mu}(\partial \Omega_0))\). Then the solution \(x^h\) to (2.5) is in \(C^m([0, T], \mathbb{H}_{\mu})\), and for \(\ell \leq m\) satisfies the bound

\[
\left\| \frac{d^\ell}{dt^\ell} x^h(t) \right\|_{\mathbb{H}_{\mu}} \leq C \left\| \gamma u^{inc}, \partial_\nu u^{inc} \right\|_{\ell+2, T, \mu} \tag{4.13}
\]

**Proof.** For \(\xi^0 := (\gamma u^{inc}, 0, \ldots, 0), \xi^1 := (\kappa_0 \partial_\nu \partial_{\nu_1} u^{inc}, 0, \ldots, 0)\) and \(\zeta := N(\xi^0, \xi^1)\), Theorem 2.7 gives that \(x^h := (u^h, w^h) \in C^m([0, T], V)\).

We write \(x^h = (x^h - \mathcal{E} \zeta) + \mathcal{E} \zeta\). Due to the boundary conditions on \(x^h\) we get that \(x^h(t) - \mathcal{E} \zeta(t) \in \text{dom}(A) = \text{dom}(A_h) \cap \ker(B_h)\) and we can estimate:

\[
\left\| x^h(t) - \mathcal{E} \zeta(t) \right\|_{\mathbb{H}_{\mu}} \leq \left\| x^h(t) - \mathcal{E} \zeta(t) \right\|_{\mathbb{H}} + \left\| A(x^h(t) - \mathcal{E} \zeta(t)) \right\|_{\mathbb{H}} \lesssim \left\| x^h(t) \right\|_V + \left\| \zeta(t) \right\|_{\mathbb{M}}.
\]

The term \(\left\| \mathcal{E} \zeta(t) \right\|_{\mathbb{H}_{\mu}}\) can be estimated by Lemma 4.3. The triangle inequality and Lemma 4.3 give

\[
\left\| x^h(t) \right\|_{\mathbb{H}_{\mu}} \leq \left\| x^h(t) - \mathcal{E} \zeta(t) \right\|_{\mathbb{H}_{\mu}} + \left\| \mathcal{E} \zeta(t) \right\|_{\mathbb{H}_{\mu}} \lesssim \left\| x^h(t) \right\|_V + \left\| \zeta(t) \right\|_M + \left\| \zeta(t) \right\|_{\mathcal{H}^{1/2}_{\mathbb{F}} \times \mathcal{H}^{-1/2+\mu}_{\mathbb{F}}}.
\]

To get to the explicit estimate in terms of the data, we use Theorem 2.7. We conclude the proof for \(m = 0\) with the remark that we can estimate \(\left\| \zeta(t) \right\|_M \lesssim t \left\| \zeta(t) \right\|_M\) since \(\zeta(0) = 0\). A similar argument applied to the differentiated equation gives the result for \(m \in \mathbb{N}\). \(\square\)
4.3 Convergence of the time discretization

We are now in position to prove the main convergence result for the time discretization.

**Theorem 4.5.** Let \( x^h := (u^h, w^h) \) be the solution to Problem (3.5) and assume \( \gamma u^{inc} \in C^{\mu+4}([0,T], H^{1/2}(\partial \Omega_0)) \) and \( \partial_\nu u^{inc} \in C^{\mu+4}([0,T], H^{-1/2+\mu}(\partial \Omega_0)) \) for some \( \mu \in [0, 1/2] \).

Assume that the Runge-Kutta method employed is A-stable and that \( Q \) is invertible. Set \( \alpha := 1 \) if the Runge-Kutta method is strictly A-stable and \( \alpha := 0 \) otherwise.

If \( x^{h,k} \) is the solution to (4.7), then the following error estimates hold for \( 0 < t_n \leq T \):

\[
\begin{align*}
\|x^h(t_n) - x^{h,k}(t_n)\|_H &\leq CT^2 k^{\min(q+\mu+1+\alpha,p)} \|\gamma u^{inc}, \partial_\nu u^{inc}\|_{p+4,T,\mu}, \\
\|x^h(t_n) - x^{h,k}(t_n)\|_\mathcal{V} &\leq CT^2 k^{\min(q+\mu+\alpha,p)} \|\gamma u^{inc}, \partial_\nu u^{inc}\|_{p+4,T,\mu},
\end{align*}
\]

where \( p \) and \( q \) denote the classical and stage order of the Runge-Kutta method employed.

For the trace component \( \psi^{h,k} \), computed in (4.4e), the following estimates can be shown:

\[
\|\psi^h(t_n) - \psi^{h,k}(t_n)\|_{\mathcal{H}^{1/2}} \leq CT^2 k^{\min(q+\mu+\alpha,p)} \|\gamma u^{inc}, \partial_\nu u^{inc}\|_{p+4,T,\mu}.
\]

The constants depend on the Runge-Kutta method, \( \mu \), and the geometry.

**Proof.** We apply the theory developed in [RSM20]. Since we are in the situation of an integrated boundary condition, we apply [RSM20, Thm. 3.4] to get (4.14a), using the regularity estimate (4.13).

By looking at the Z-transforms, it is easy to see that \( Y^{h,k} := \partial_\nu X^{h,k} = A_\nu X^{h,k} \) solves the following problem

\[
\begin{align*}
Y^{h,k}(t_n) &= y^{h,k}(t_n)1 + k[Q \otimes A_\nu]Y^{h,k}(t_n), \\
B_\nu Y^{h,k}(t_n) &= \left(\partial_\nu (\partial_\nu)^{-1} \xi(t_n), 0, 0\right) = N_\nu \xi(t_n), \\
y^{h,k}(t_{n+1}) &= R(\infty)y^{h,k}(t_n) + b^T Q^{-1} Y^{h,k}(t_n),
\end{align*}
\]

while \( y^h := A_\nu x^h \) solves \( \dot{y}^h = A_\nu y^h \) and \( B_\nu y^h = N_\nu \xi \). This means we can apply [AMP03, Thm. 1 or 2] to get the following error estimate:

\[
\begin{align*}
\|A_\nu(x^h(t_n) - x^{h,k}(t_n))\|_H &\lesssim Tk^{\min(q+\mu+\alpha,p)} \sup_{j=0}^{p+2} \|x^h(t)\|_{H} \\
&\lesssim T^2 k^{\min(q+\mu+\alpha,p)} \|\gamma u^{inc}, \partial_\nu u^{inc}\|_{p+4,T,\mu}.
\end{align*}
\]

Together with the \( H \)-estimate for \( x^h(t_n) - x^{h,k}(t_n) \) we can estimate the \( \mathcal{V} \)-norm. The trace theorem then immediately gives (4.14c).

\[ \square \]

**Theorem 4.6.** Consider the same setting as in Theorem 4.5 and further assume that \( \gamma u^{inc} \in C^{\mu+4}([0,T], H^{1/2}(\partial \Omega_0)) \) and \( \partial_\nu u^{inc} \in C^{\mu+4}([0,T], H^{-1/2+\mu}(\partial \Omega_0)) \) for some \( \mu \in [0, 1/2] \).
If, in addition, the Runge-Kutta method is also stiffly accurate, then we can estimate \( \phi^h \) as defined in (4.4e) by:

\[
\left\| \phi^h(t_n) - \phi^{h,k}(t_n) \right\|_{H^{-1/2}} \leq CT^{2k} \gamma \|u^\text{inc}, \partial_{\nu}u^\text{inc}\|_{p+5,T,\mu},
\]

where the rate \( r_\phi \) is given by

\[
\begin{cases} 
q + \mu + \alpha - 1/2 & \text{for } q + \alpha < p \\
q + \alpha + \frac{\mu}{2} & \text{for } q + \alpha = p \\
p + \frac{\alpha}{2} & \text{for } q + \alpha > p.
\end{cases}
\]

Proof. Reusing the notation from Theorem 4.5, write \( \mathbf{y}^h =: (\nu^h, z^h) \). In order to estimate \( \phi^h - \phi^{h,k} \) we need to control \( \nabla \cdot z^h - \nabla \cdot z^{h,k} \). This can be estimated by using [RSM20, Thm. 3.5]. Together with the regularity estimate (4.13) we get the rate

\[
\left\| \nabla \cdot z^h - \nabla \cdot z^{h,k} \right\|_{H} \lesssim T^{2k_{\text{min}}(q+\mu,p)+\alpha-1} \|u^\text{inc}, \partial_{\nu}u^\text{inc}\|_{p+5,T,\mu}.
\]

Define \( r_0 := \min(q + \mu + \alpha, p) \) and \( r_1 := \min(q + \mu, p) + \alpha - 1 \) for the convergence rates of \( \|z^h - z^{h,k}\|_{H} \) and \( \|\nabla \cdot z^h - \nabla \cdot z^{h,k}\|_{H} \), respectively.

Setting \( e_\ell := z^h_\ell - z^{h,k}_\ell \) for the \( \ell \)-th component of the error, we can calculate for \( \eta \in H^{1/2}(\partial \Omega_\ell) \) and \( v \in H^1(\mathbb{R}^d) \) with \( \gamma^\text{int}_\ell v = \gamma^\text{ext}_\ell v = \eta \):

\[
\left\langle e_\ell, v \right\rangle_{\partial \Omega_\ell} \lesssim \left\| e_\ell \right\|_{L^2(\mathbb{R}^d \setminus \partial \Omega_\ell)} + \left\| e_\ell v \right\|_{L^2(\mathbb{R}^d \setminus \partial \Omega_\ell)} \left( \left\| \nabla v \right\|_{L^2(\mathbb{R}^d \setminus \partial \Omega_\ell)} + k^{r_0-\gamma_\ell} \left\| v \right\|_{L^2(\mathbb{R}^d \setminus \partial \Omega_\ell)} \right).
\]

We are still free to pick the precise lifting \( v \). By [Say16, Prop. 2.5.1], we have for arbitrary \( \beta > 0 \)

\[
\inf \{ k^{-\beta} \left\| v \right\|_{L^2} + \left\| \nabla v \right\|_{L^2} : v \in H^1(\mathbb{R}^d), \gamma^\text{int}_\ell v = \eta \} \leq C_\beta \max\{1, k^{-\beta/2}\} \|\eta\|_{H^{1/2}(\partial \Omega_\ell)}.
\]

We thus get the convergence rate:

\[
\left\| \phi^h(t_n) - \phi^{h,k}(t_n) \right\|_{H^{-1/2}} \lesssim C(u^\text{inc}) T^{2k_{\text{min}} + (r_1 - r_0)/2}.
\]

The full statement then follows by explicitly checking the different cases and working out the dependencies of \( C(u^\text{inc}) \).

\[\Box\]

### 4.4 Convergence of the fully discrete scheme

In this section, we collect the previous convergence results for the space and time discretization to give explicit convergence rates for the fully discrete systems. In order to quantify the convergence rates of the full discretization, we make the following assumption on the spaces \( X_h \) and \( Y_h \) (see Section 2.3 on how to construct spaces satisfying these assumptions).
Theorem 4.7. Let the incident wave satisfy $\gamma u^{\text{inc}} \in C^{p+5}([0, T], H^{1/2}(\partial \Omega))$ as well as $\partial_t u^{\text{inc}} \in C^{p+4}([0, T], H^{-1/2+\mu}(\partial \Omega))$ for some $\mu \in [0, 1/2]$.

Let $p$ denote the classical order of the Runge-Kutta method and $q$ its stage order. Assume that the method is $A$-stable and $Q$ is invertible. Set $\alpha := 1$ if the method is stiffly accurate (i.e., $|r(z)| < 1$ for $0 \neq z \in i\mathbb{R}$ and $r(\infty) \neq 1$), and set $\alpha := 0$ otherwise. Let $\lambda := (\phi, \psi)$ be the exact solution of (3.11), and $x := (u, w)$ be the corresponding exact solution to (2.5). Let $\lambda^{h,k} := (\phi^{h,k}, \psi^{h,k})$ denote the solutions to (4.4), and $x^{h,k} = (u^{h,k}, w^{h,k})$ the post-processing using the representation formula (4.4d) and (4.4e).

Then the following estimates hold for $t_n = nk$ with $t_n \leq T$:

$$\|x(t_n) - x^{h,k}(t_n)\|_V \lesssim T \sum_{j=0}^{2} \left[ \max_{0 \leq \tau \leq t_n} \inf_{\psi_{h,j} \in X_h} \|(\psi^{(j+1)} - \psi_{h,j}, \phi^{(j)} - \phi_{h,j})\| \right]$$

$$+ T^2 \kappa^{\min(q+\mu+1+\alpha,p)} \|(\gamma u^{\text{inc}}, \partial_t u^{\text{inc}})\|_{p+4,T,\mu}.$$ 

If the method is stiffly accurate, we get:

$$\|\phi(t) - \phi^{h,k}(t_n)\|_{\mathcal{H}^{-1/2}} \lesssim T \sum_{j=0}^{3} \left[ \max_{0 \leq \tau \leq t_n} \inf_{\psi_{h,j} \in X_h} \|\|(\psi^{(j+1)} - \psi_{h,j}, \phi^{(j)} - \phi_{h,j})\| \right]$$

$$+ T^2 \kappa^{r\phi} \|(\gamma u^{\text{inc}}, \partial_t u^{\text{inc}})\|_{p+5,T,\mu},$$

where the rate is given by

$$r\phi := \begin{cases} 
q + \alpha + \frac{1}{2} & \text{for } q + \alpha < p \\
q + \alpha - \frac{\mu - 1}{2} & \text{for } q + \alpha = p \\
p + \frac{\alpha - 1}{2} & \text{for } q + \alpha > p.
\end{cases}$$

The implied constant $C(u^{\text{inc}})$ depends on the geometry and the Runge-Kutta method but is independent of the incident wave, $h$ and $k$ and $T$.

Proof. We estimate

$$\|x(t_n) - x^{h,k}(t_n)\|_V \lesssim \|x(t_n) - x^h(t_n)\|_V + \|x^h(t_n) - x^{h,k}(t_n)\|_V.$$

The convergence of the semi-discretization in space is quasi-optimal by Theorem 3.2. The convergence with respect to time can be estimated by Theorem 4.5, where Lemma 4.3 and Corollary 4.4 tell us that we may use the value $\mu = 1/2$. The bounds on $\phi - \psi^{h,k}$ follows from the continuity of the trace operator. The trace on $\phi - \phi^{h,k}$ follows along the same lines but using the bounds proved in Theorem 3.2 and Theorem 4.6. \qed

Assumption 4.8. For a parameter $r \in \mathbb{N}_0$, the discrete spaces $X_h$ and $Y_h$ satisfy the following approximation property for all $\phi = (\phi_\ell)_{\ell=0}^L \in X$ with $\phi_\ell \in H^{r+1}_p(\partial \Omega_\ell)$ and $\phi_0^{\text{inc}} \in C^{r+5}(\partial \Omega)$.
all $\psi := (\psi_\ell)_{\ell=0}^L \in \mathcal{Y}$, $\psi_\ell \in H_{\text{pw}}^{r+2} (\partial \Omega_\ell)$ such that the lifting in (2.3b) is a continuous function on $\Gamma$: 

$$\inf_{\phi_h \in \mathcal{X}_h} \| \phi - \phi_h \|_{H^{-1/2}} \leq C h^{r+3/2} \sum_{\ell=0}^L \| \phi_\ell \|_{H_{\text{pw}}^{r+1} (\partial \Omega_\ell)},$$  

(4.18a)

$$\inf_{\psi_h \in \mathcal{Y}_h} \| \psi - \psi_h \|_{H^{1/2}} \leq C h^{r+3/2} \sum_{\ell=0}^L \| \psi_\ell \|_{H_{\text{pw}}^{r+2} (\partial \Omega_\ell)},$$  

(4.18b)

where the constant $C$ may depend on $r$ and the geometry but not on $h$, $\phi$ or $\psi$.

Since we have to implement the scheme in practice, we only consider the case $\partial_\nu u_{\text{inc}} \in L^2 (\partial \Omega_0)$, i.e., $\mu = 1/2$. Then the following theorem holds.

**Corollary 4.9.** Let the assumptions of Theorem 4.7 hold. Assume that the traces of the exact solution satisfy $\phi_\ell \in C^3 ([0, T], H_{\text{pw}}^{r+1} (\partial \Omega_\ell))$, $\psi_\ell \in C^3 ([0, T], H_{\text{pw}}^{r+2} (\partial \Omega_\ell))$ for some $r \in \mathbb{N}_0$. Also assume that $\psi^{(j)}$ admits a lifting to $H^1 (\mathbb{R}^d)$ that is continuous on $\Gamma$ for $j = 0, \ldots, 3$. Assume $d \leq 3$ and let Assumption 4.8 be satisfied for $\mathcal{X}_h$ and $\mathcal{Y}_h$ with the same parameter $r$ as in the regularity assumptions. Then the following estimates hold for $t_n = nk$ with $t_n \leq T$:

$$\| x(t_n) - x_h^{h,k}(t_n) \|_{\mathcal{Y}} \leq C(u_{\text{inc}}) \left( Th^{r+3/2} + T^2 k^{\min(q+\alpha+1/2, p)} \right),$$  

(4.19a)

$$\| \psi(t_n) - \psi_h^{h,k}(t_n) \|_{H^{1/2}} \leq C(u_{\text{inc}}) \left( Th^{r+3/2} + T^2 k^{\min(q+\alpha+1/2, p)} \right),$$  

(4.19b)

If the method is stiffly accurate, we get:

$$\| \phi(t) - \phi_h^{h,k}(t_n) \|_{H^{-1/2}} \leq C(u_{\text{inc}}) (Th^{r+3/2} + T^2 k^{r}).$$  

(4.19c)

where the rate given by

$$r_\phi := \begin{cases} 
q + \alpha & \text{for } q + \alpha < p \\
q + \alpha - \frac{1}{2} & \text{for } q + \alpha = p \\
p + \frac{p-1}{2} & \text{for } q + \alpha > p.
\end{cases}$$

The constant $C(u_{\text{inc}})$ depends on the incident wave, the geometry, the Runge-Kutta method, and the constants in Assumption 4.8, but is independent of $h$ and $k$ and $T$.

**Proof.** Follows directly from Theorem 4.8, the regularity assumptions and Assumption 4.8.

### 5 Particular geometric configurations

In this section we present two simple geometric configurations that fit into our framework. We show how in these cases, using the spaces presented in Section 2.3, the method analyzed in this paper can be considered equivalent to known methods in the literature.
5.1 Multiple homogeneous scatterers

Assume that $\Omega_\ell$ ($\ell = 1, \ldots, L$) are bounded Lipschitz domains such that each of the boundaries $\partial \Omega_\ell$ is connected and these boundaries are mutually disjoint. In this case

$$H^{\pm 1/2}(\partial \Omega_0) \equiv \prod_{\ell=1}^{L} H^{\pm 1/2}(\partial \Omega_\ell).$$

Using this identification we can establish isomorphisms

$$\prod_{\ell=1}^{L} H^{1/2}(\partial \Omega_\ell) \ni (\psi_\ell)_{\ell=1}^{L} \mapsto ((\psi_1, \ldots, \psi_L), \psi_1, \ldots, \psi_L) \in \mathcal{Y},$$

$$\prod_{\ell=1}^{L} H^{-1/2}(\partial \Omega_\ell) \ni (\phi_\ell)_{\ell=1}^{L} \mapsto (-(\phi_1, \ldots, \phi_L), \phi_1, \ldots, \phi_L) \in \mathcal{X}.$$  

In some way, the second isomorphism can be understood as changing the orientation of the normal vector exterior to the unbounded domain $\Omega_0$ to make it point towards it. The boundary integral formulation that we got before (see (3.11)) can be reformulated in the reduced representation. What we obtain is the Costabel-Stephan system of TDBIE for transmission problems of [QS16], analyzed as a first order system; see also [Qiu16]. The frequency domain version of this reduced system is the classical formulation in [CS85].

5.2 Layered scatterers

Another interesting simplified situation, already considered in [Qiu16], is the one of scatterers containing separate inclusions, which can themselves contain inclusions, etc. We can represent the geometric configuration as a tree, whose nodes are the domains $\Omega_\ell$, rooted at $\Omega_0$, and whose edges are the connected components of $\Gamma$, so that an edge connecting two vertices is the common boundary of both domains. We can number the components of $\Gamma$ as $\Gamma_i$, $i = 1, \ldots, L$ and assign a parent node $p(\ell) \in \{0, \ldots, L\}$ to each node $\ell \geq 1$ so that

$$\partial \Omega_\ell \cap \partial \Omega_{p(\ell)} = \Gamma_\ell, \quad \ell \in \{1, \ldots, L\}$$

and

$$\partial \Omega_\ell = \Gamma_\ell \cup (\cup \{\Gamma_i : p(i) = \ell\}), \quad \ell \in \{0, \ldots, L\}$$

where we denote $\Gamma_0 := \emptyset$ to unify notation; see Figure 5.1 for a schematic representation. We can thus identify

$$H^{\pm 1/2}(\partial \Omega_\ell) \equiv H^{\pm 1/2}(\Gamma_\ell) \times \prod_{\{i : p(i) = \ell\}} H^{\pm 1/2}(\Gamma_i)$$
and use this to define isomorphisms

\[
\prod_{i=1}^{L} H^{1/2}(\Gamma_i) \ni (\psi_i)_{i=1}^{L} \mapsto \left( (\psi_i)_{p(i)=0}, (\psi_i)_{p(i)=\ell} \right)^{L}_{\ell=0} \in \mathcal{Y},
\]

\[
\prod_{i=1}^{L} H^{-1/2}(\Gamma_i) \ni (\phi_i)_{i=1}^{L} \mapsto \left( - (\phi_i)_{p(i)=0}, (\phi_i)_{p(i)=\ell} \right)^{L}_{\ell=0} \in \mathcal{X},
\]

morally corresponding to fixing all normals so that they point towards the exterior of the closed boundaries \(\Gamma_i\).

Figure 5.1: A cartoon representing two scatterers with inclusions, and the corresponding tree. The arrows point to the parenting (surrounding) domain and are tagged with the common intersection.

### 6 Numerical examples

We implemented the proposed method in 2D, using the algorithm for fast solutions of CQ-problems described in [BS09]. For the implementation of the standard BEM operators, we relied on the code developed by F. -J. Sayas and his group at the University of Delaware. Assembling the matrices for Problem (4.4) can be done fairly simply using existing boundary element code with the spaces described in Section 2.3. In order to do so, we only have to provide the transfer matrices \(\mathcal{R}^{\top} : \mathcal{Q}_h \times \mathcal{P}_h \rightarrow \mathcal{Y}_h \times \mathcal{X}_h\), which map the degrees of freedom from the boundary element spaces \(\mathcal{P}_h\) and \(\mathcal{Q}_h\) to the standard BEM spaces on each subdomain (respecting the orientation of the surfaces in the case of \(\mathcal{P}_h\)).

The discretization of (4.4) is equivalent to: find \(\Lambda^{h,k} := (\Psi^{h,k}, \Phi^{h,k}) \in [\mathcal{Q}_h \times \mathcal{P}_h]^m\) such that

\[
\hat{\mathcal{R}} \hat{\mathcal{Q}}_h C(\partial_k) \hat{\mathcal{Q}}^{-1}_h \mathcal{R}^{\top} \Lambda^{h,k} = \hat{\mathcal{R}} \hat{\mathcal{Q}}_h (C(\partial_k) - \frac{1}{2} I) \hat{\mathcal{Q}}^{-1}_h J(\partial_k) \hat{\Xi}^k
\]

and then using the transfer matrices \(\mathcal{R}\) to get back the functions \(\Lambda^{h,k} := (\Psi^{h,k}, \Phi^{h,k}) := \mathcal{R}^{\top} \Lambda^{h,k}\) in \([\mathcal{Y}_h \times \mathcal{X}_h]^m\).
When using the approach from [BS09] for solving the convolution system, we need to solve \( n = \frac{T}{k} \) problems in the frequency domain. Since the operator \( C(s) \) appears on both the left- and right-hand side, it only has to be assembled once if we combine the steps for computing the right-hand side and solving. The computation of \( J(\partial_k) \) does not incur any significant additional cost, as it corresponds to a multiplication with the matrix \( k(\delta(z))^{-1} \) of the second component of the right-hand side during the CQ-algorithm.

As the model geometry, we use a simple checkerboard pattern consisting of 2 \( \times \) 2 unit squares and the wave speed vector \( (\kappa_\ell)_{\ell=0}^4 := (2, 3, 1, 5, 7) \).

In order to be able to quantify the convergence, we prescribe an exact solution in the following way: On each subdomain \( \Omega_\ell \) for \( \ell = 1, \ldots, L \), the solution \( u_\ell \) is given as a plane wave with

\[
u_\ell(x, t) := G(d_\ell \cdot x - \kappa_\ell(t - t_{lag})), \quad \text{where} \quad G(z) := e^{-2z/\alpha} \sin(z).
\]

Here, \( d_\ell \in \mathbb{R}^2 \) denotes the direction of the wave, and we chose the following parameters:

\[
d_\ell := \begin{cases} \frac{1}{\sqrt{2}} (1, -1)^T & \text{if } \ell \text{ is even} \\ \frac{1}{\sqrt{2}} (1, 1)^T & \text{if } \ell \text{ is odd} \end{cases}
\]

\( t_{lag} = 5/2 \), and \( \alpha := 1/4 \). In order not to have to concern ourselves with radiation conditions, we chose \( u_0 := 0 \) for the solution in the exterior. For the boundary traces, we made the following choice, using the function \( \chi(t) := t^9 e^{-2t} \) to ensure homogeneous initial conditions:

\[
\psi(x, t) := \chi(t) \sin(x_1) \cos(x_2) \quad \text{and} \quad \phi(x, t) := \chi(t) \cos(x_1) \sin(x_2).
\]

(These functions are to be understood as functions on the skeleton. \( \phi \) is then built by restricting to the subdomains and multiplying with a sign function as is done in Section 2.3, whereas \( \psi \) is obtained via the restrictions to the subdomains.) The boundary data \( \xi^0 \) and \( \xi^1 \) were then calculated accordingly in order to yield these solutions.

**Example 6.1.** In this example, we are interested in the convergence with respect to the time discretization. Therefore, we fix a fine uniform mesh with \( h \approx 0.03125 \) and use \( r = 4 \), i.e., quartic polynomials for the discontinuous space and quintic for the continuous splines. We apply a two-stage Radau IIA method, which satisfies \( q = 2 \) and \( p = 3 \). By Theorem 4.9, we expect order \( O(k^3) \) for the Dirichlet trace and \( O(\sqrt{k}^{2.75}) \) for the Neumann trace when using (4.4). As a comparison, we also compute the solutions using (4.8). Figure 6.1a shows the result. Most notably, it shows that when using (4.4), the Neumann trace outperforms our predictions and converges with the full classical order. We also see that using (4.8) gives a reduced order of 2 when approximating \( \lambda \).

**Example 6.2.** We perform the same experiment as in Example 6.1, but use a 3-stage Radau IIA method. We expect orders \( O(k^{4.5}) \) and \( O(k^3) \) for the Dirichlet and Neumann traces respectively. Again the method (4.4) outperforms our expectations, giving the full classical order 5, while using (4.8) gives a reduced rate.
Figure 6.1: Comparison of discretization schemes

(a) Convergence rates using a 2-stage Radau IIa method.
(b) Convergence rates using a 3-stage Radau IIa method.

Figure 6.2: Convergence rates w.r.t. the spatial discretization

(a) Convergence $\psi - \psi^h$
(b) Convergence $\lambda - \lambda^h$
Remark 6.3. Examples 6.1 and 6.2 showed that the proposed method often outperforms the predictions of the theory. While a full theoretical explanation for this effect is still lacking, partial answers can be found in [MR20] for a simpler model problem.

Example 6.4. We use the same model problem as in Example 6.1, but we fix the time discretization at \( k \approx 0.015 \) using a 3-stage Radau IIa method. We vary the approximation in space by performing successive uniform refinements of the grid, and compare different polynomial degrees \( s = 0, \ldots, 3 \). Since it is easier to compute, we consider the \( L^2 \)-norm of the errors. In Figure 6.2 we observe the optimal convergence rates until an error of \( \approx 10^{-6} \) is reached, at which point other error contributions prohibit further convergence.

Example 6.5. We consider a more realistic scattering problem for which no exact solution is available. Errors are estimated by comparing with a reference solution computed to higher accuracy. We consider a 3-by-3 checkerboard domain. The wavenumbers are given by

\[
\begin{bmatrix}
5 & 0.2 & 5 \\
0.2 & 5 & 0.2 \\
5 & 0.2 & 5
\end{bmatrix},
\]

and in the exterior it is taken to be 1. This obstacle is hit by an incoming wave of the form \( u^{inc}(x,t) := H(x \cdot d - t) \) with \( d := [1,0]^T \) and

\[
H(x) := x^5 \left( 1 - 5(x-1) + 15(x-1)^2 - 35(x-1)^3 + 70(x-1)^4 - 126(x-1)^5 \right)
\]

for \( x \in (0,1) \) and \( H(x) := 1 \) for \( x \geq 1 \). The precise function was taken from the examples of the DeltaBEM package [del20].

Figure 6.3 depicts the evolution of the solution over time. Once the incoming wave hits the scatterer, we observe complicated intersections, especially at the triple-points where the wave number changes between domains. Figure 6.5 presents the convergence of the method, where we compared the solution to the one obtained by halving the step size. The boundary element grid was taken fixed with mesh size \( 2^{-6} \) and polynomials of degree 4 and 5 for discretizing \( \mathcal{H}^{-1/2} \) and \( \mathcal{H}^{1/2} \) respectively. Due to the non-smooth structure of the solution, we observe a large preasymptotic regime, clouding the true asymptotic convergence rate. Nevertheless, for small time steps we still observe a high order of convergence.
